ABSTRACT
Blood vessel in retinal image plays a vital role in medical diagnosis of many diseases. Diabetic retinopathy is one of the diseases which damages the retina and leads to blindness. Segmentation of blood vessels is helpful for ophthalmologists and this paper presents a new automatic method to extract blood vessels with high accuracy. This algorithm is comprised of optimized Gabor filter with local entropy thresholding for vessels segmentation under various normal or abnormal conditions. The frequency and orientation of Gabor filter are tuned to match that of a part of blood vessels to be enhanced in a green channel image. Segmentation of blood vessels pixels are classified by local entropy thresholding technique in this method. The performance of the proposed algorithm is evaluated by MATLAB software with DRIVE database.

General Terms
Bio-informatics, Computer Aided Diagnosis system

Keywords
Retinal image, Blood vessels, Diabetic retinopathy, Optimized Gabor filter, Local entropy thresholding.

1. INTRODUCTION
Diabetic retinopathy (DR) is the result of damage caused by diabetes to the small blood vessels located in the retina. Blood vessels damaged from diabetic retinopathy can cause vision loss. Diabetic retinopathy is a leading cause of adult blindness, and screening can reduce the incidence. Screening just increases the chances that a condition will be avoided, found early, or are able to be cured. It is widely recommended that all persons with diabetes mellitus should be regularly screened for diabetic retinopathy [1].

Computer based analysis for automated segmentation of blood vessels in retinal images will help ophthalmologists screen larger populations for vessel abnormalities. A wide variety of approaches have been proposed for retina blood vessels segmentation. Many image processing methods proposed for retinal vessels extraction [4] [5] [6] [7] [8] [9] [10]. This literature is based on optimized Gabor filter with local entropy thresholding. Gabor filters have been widely applied to image processing and computer vision application problems such as face recognition and texture segmentation [8]. Optimized Gabor filter methods often produce false positive detections and fail to detect vessel of different widths. Also detection process much more complicated when retinal image abnormal condition.

This paper has been proposed a much robust and fast method of retinal blood vessels extraction using optimized Gabor filter with local entropy thresholding.

2. MATERIALS AND METHODS
DRIVE database [30] is used for this analysis. Every image was capture at 584x565 pixels, 8 bits per color in TIFF format.

Blood vessels usually have poor local contrast compare to background. The proposed method uses the following steps: (i) Green channel extraction, (ii) Adaptive Histogram Equalization, (iii) Optimized Gabor filter, (iv) Local Entropy Thresholding (v) Binary conversion. The green channel is inverted before the application of the Gabor Filter transform to it, so that the vessels appear brighter than the background. Fig.1 shows the overall procedure of the proposed method.

2.1 Preprocessing
Preprocessing is applied to eliminate the noises in the fundus image. Regarding the acquisition process, retinal images have often low contrast that cause to hardly detect the blood vessels. This method is to improve the image dynamic range to prepare images for next step, detection the blood vessels, and attain to higher accuracy and precision of segmentation. Concerning our purpose, contrast enhancement, the green channel of colored retinal images is used, because compare to other channels it has the highest contrast [4]. Combining advantages of brightness in red channel decreasing the contrast between the abnormalities and the retinal
background; this helps to reduce some responses from abnormalities which do not resemble any blood vessels that would otherwise decrease the performance of blood vessels segmentation methods. Contrast-limited adaptive histogram equalization is used for this analysis that enhancing the contrast of the green channel retinal image.

2.2 Optimized Gabor Filter

Gabor filters have been widely used for multi-directional analysis in image processing. In this algorithm, optimized Gabor filter is used for detecting the blood vessel in retinal image. The optimized Gabor filters are a set of orientation and frequency sensitive band pass filters which have the optimal localization in both the frequency contents of the patterns [8]. The optimized Gabor filter kernels are sinusoids modulated.

$$\sigma_x = k$$  \hspace{1cm} (1)

$$\frac{\sigma_y}{\gamma} = \frac{\sigma_x}{\gamma}$$ \hspace{1cm} (2)

$$x_\theta = x \cos \theta + y \sin \theta$$ \hspace{1cm} (3)

$$y_\theta = -x \sin \theta + y \cos \theta$$ \hspace{1cm} (4)

Optimized Gabor filter kernel:

$$g_\theta(x, y) = \exp\left(-\frac{1}{2}\left(\frac{x_\theta^2}{\sigma_x^2} + \frac{(y_\theta)^2}{\sigma_y^2}\right)\right) \cos(2\pi \frac{x_\theta}{\lambda} + \psi)$$  \hspace{1cm} (5)

Where,

$$\sigma_x$$: Standard deviation of Gaussian in x direction along the filter that determines the bandwidth of the filter.

$$\sigma_y$$: Standard deviation of Gaussian filter that controls the orientation selectivity of the filter.

$$\theta$$: Orientation of the filter, an angle of zero gives a filter that responds to vertical features.

$$\lambda$$: Wavelength of the cosine factor of the Gabor filter kernel i.e. preferred wavelength of this filter.

$$\gamma$$: Spatial aspect ratio, specifies the ellipticity of the support of the Gabor function.

$$\psi$$: Phase offset

The optimized Gabor filter kernel (9x7 matrix) is rotated in different rotations with the optimized parameters set as follows:

$$\sigma_x \in [3.91, 4.0], \lambda \in [5.1, 5.3], \gamma \in [1.2, 1.4]$$

$$\sigma_x = 3.91$$

$$\lambda = 5.1$$

$$\gamma = 1.3$$

$$\psi = 2\pi$$

$$\sigma_x$$ is required so that the shapes of the filter are invariant to the scale. The width of the vessels is found to lie within a range of 2-14 pixels (40-200µm). Here, $$\lambda$$ and $$\gamma$$ values maintain false positive rate. $$\psi$$ always (2$$\pi$$) rotation phase in this method. The optimized parameters are to be derived by taking into account of size of the lines structures to be detected. Only six optimized Gabor filters with different orientations (0 to 360° intervals of sixty degrees) are used to convolve with the preprocessing image. The magnitude of each response is retained and combined to generate the result image.

2.3 Local Entropy Thresholding

An image can be viewed as an information source with a probability vector described by its grey-level image histogram, the entropy of the histogram can be used to represent a certain level of information contained in the image. Pun [16] and Kapur et al. [17] had taken this concept to derive entropy thresholding methods. However, their approaches did not take into account the correlation among grey levels. As a result, two different images with an identical image histogram will result in the same threshold value [18].

One way to resolve this problem is to consider the grey-level co-occurrence matrix, which contains the information of grey-level transitions in an image. In the proposed method the grey-level co-occurrence matrix developed by Haralick et al. [19] is used to derive the Haralick texture feature for retinal image segmentation. The Haralick texture feature chosen is the entropy of the retinal image.

In order to perform the proper extraction of the enhanced segments from the Gabor filter response images, an effective thresholding method is required.

Assume that a Gabor filter response image has a size of M x N with L grey levels denoted by $$G = \{0, 1, \ldots, L-1\}$$. A co-occurrence matrix of an image is an L x L square matrix, denoted by $$T = [t_{ij}]_{L \times L}$$, whose elements are specified by the numbers of transitions between all pairs of grey levels in $$G = \{0, 1, \ldots, L-1\}$$ in a particular way.

That gives an idea about the transition of intensity between adjacent pixels, indicating spatial structural information of image. Depending upon the ways in which the gray level i follows gray level j, different definition of co-occurrence matrix are possible. Here, we made the co-occurrence matrix asymmetric by considering the horizontally right and vertically lower transitions. Let $$t_{ij}$$ be the ($$i,j$$)th entry of the co-occurrence matrix. Then the probability of co-occurrence $$p_{ij}$$ of gray levels i and j is Normalizing the probability within individual quadrants, such that the sum of probabilities of each quadrant equals to one, we get the following cell probability.
Let \( t \) be a value used to threshold an image. It partitions the co-occurrence matrix into four quadrants, namely, A, B, C and D. We assume that pixels with grey levels above the threshold are assigned to the foreground (corresponding to objects), and those equal to or below the threshold are assigned to the background. Then quadrants A and C correspond to local transitions within background and foreground, respectively, whereas quadrants B and D are joint quadrants which represent joint transitions across boundaries between background and foreground. The probabilities associated with each quadrant are then given by

\[
P_{ij} = \sum \sum_{i,j}^{t} \]

Obviously \( 0 \leq P_{ij} \leq 1 \)

The second order local entropy of the object can be defined as

\[
H^{(A)}(s) = -\frac{1}{2} \sum \sum_{i=0}^{t} P_{ij}^{(1)} \log_{2} P_{ij}^{(1)}
\]

Similarly the background written as

\[
H^{(C)}(s) = -\frac{1}{2} \sum \sum_{i=0}^{t} P_{ij}^{(2)} \log_{2} P_{ij}^{(2)}
\]

The entropy threshold determines the optimal threshold \( t^* \) by maximum of the entropy curve. \( t^* \) is used as the threshold for segmentation of the retinal image. This threshold find it automatically form the Entropy-Threshold Curve.
positive defines the fraction of pixels erroneously classified as vessel pixels. Average sensitivity is 98.5%. The computational time of whole process of our method takes approximate 2 seconds for each retinal image.

Accuracy ($A_c$)

$$A_c = \frac{TP + TN}{TP + TN + FP + FN}$$

(13)

Sensitivity ($S_e$)

$$S_e = \frac{TP}{TP + FN}$$

4. CONCLUSION
A fully automated retinal blood vessels segmentation method has been presented. In this paper, first introduce optimized Gabor filter with local entropy thresholding for vessels extraction. The threshold value obtained by calculating the entropy feature from the gray level co-occurrence matrix of the optimal Gabor filter retinal image can be one of the ways of segmentation of retinal images. This analysis demonstrated higher true positive rate and reduce false detection in retinal image. The performance of the proposed method is evaluated by comparing DRIVE database images [30]. This method average accuracy (Acc) is 97.94% and average sensitivity (Se) is 98.5%. The accuracy of the algorithm may be improved by effective noise reducing techniques. The algorithm has less computations and elapsed time is approximate 2 seconds for segmentation of one retinal image. This analysis may also be applied to publically available STARE database. This method can be applied for image registration purpose to track the change in fundus images for monitoring diabetic retinopathy. In this automated segmentation method will help ophthalmologists screen larger populations for blood vessels abnormalities in retinal image.
