ABSTRACT
This paper presents chance constrained multi-objective capacitated transportation problem based on fuzzy goal programming problem. Generally, in transportation problem the capacity of each origin and the demand of each destination are random in nature. The inequality constraints representing supplies and demands are probabilistically described. In many real situations, there are capacity restrictions on units of commodities which are shipped from different sources to different destinations. In the model formulation, supply and demand constraints are converted into equivalent deterministic forms. Then, we define the fuzzy goal levels of the objective functions. The fuzzy objective goals are then characterized by the associated membership functions. In the solution process, two fuzzy goal programming models are considered by minimizing negative deviational variables to obtain compromise solution. Distance function is used in order to obtain the most compromise optimal solution. In order to demonstrate the effectiveness of the proposed approach, an illustrative example of chance constrained multi-objective capacitated transportation problem is solved.

General Terms
Transportation, Optimization

Keywords
Fuzzy Goal Programming, Chance Constrained Programming, Transportation Problem, Capacitated Transportation Problem, Randomness, Membership function, Multi objective decision making.

1. INTRODUCTION

Dantzig [16,17] developed the stochastic programming. In stochastic programming, the parameters are described by random variables with known distribution. The chance constrained programming (CCP) was introduced by Charnes and Cooper in 1963[18]. In 1988, Hassin and Zemel [19] studied probabilistic analysis of the capacitated transportation problem. They showed that asymptotic conditions on the supplies and demands assure a feasible solution to the problem.

In 1992, Bit et al. [20] studied the fuzzy programming approach to multi criteria decision making transportation problem. The coefficients in the objective functions and right hand side parameters of the constraints are crisp numbers. In 1994, Bit et al. [21] also developed a fuzzy programming approach to chance constrained multi objective TP. They considered parameters as standard normal, log-normal, uniform random variables.

In the recent past, Pramanik and Roy [22] Pramanik and Dey [23] studied FGP by considering only negative deviational variables in achievement functions. In this paper, the concept of Pramanik and Dey [23] is further extended to chance constrained FGP and its application in solving multi objective capacitated transportation problem (MOCTP).The right hand parameters of the constraints are random variables of known mean and variance. We consider the random variables as normal distribution with given mean and variance and we convert the normal random variables into standard normal random with zero mean, unit variance. To convert the CCP with known confidence level into deterministic constraints, we use standard normal distribution table.

Rest of the paper is organized in the following way: Section 2 describes multi-objective transportation...
problem. Section 3 presents mathematical model of chance constrained multi-objective capacitated transportation problem. Section 4 is devoted to present proposed FGP formulation of chance constrained multi-objective capacitated transportation problem. Section 7 provides the selection of compromise solution using distance function. In Section 6, illustrative numerical example is solved to show the efficiency of the proposed approach. Section 7 presents the concluding remarks. Finally, Section 8 adds necessary references.

2. MULTI-OBJECTIVE CAPACITATED TRANSPORTATION PROBLEM

A transportation problem helps us to find out the way in which resources are allocated properly from origins to destinations so that total transportation costs, time, deterioration during transportation etc. would be minimal.

We consider p sources (origins) O_i (i = 1, 2, ..., p) and q destinations D_j (j = 1, 2, ..., q). At each source O_i (i = 1, 2, ..., p), let a_{ij} be the amount of product to be shipped to the q destinations D_j in order to satisfy the demand b_j (j = 1, 2, ..., q) there. In many practical problems, a_i and b_j cannot be deterministically provided. Here, a_i, b_j are considered as random variables with known distribution.

In addition, there exists a penalty c_{ij}^k associated with transporting a unit of product from source O_i to destination D_j for the k-th criterion. In general, c_{ij}^k denotes the transportation costs, delivery time, damage charges (loss of quality and quantity of transported items), underused capacity, etc. Let x_{ij} be the variable that represents the unknown quantity transported from i-th origin to j-th destination. Since, we are interested in capacitated TP, there are limitations on the amount of resources allocated in different cells. Let r_{ij} be the maximum amount of quantity transported from i-th source to j-th destination i.e. x_{ij} ≤ r_{ij}. This restriction is called the capacitated restriction on the route i to j.

Considering k penalty criteria, the mathematical model for MOCTP with chance constraints can be written as:

\[ \min Z^k = \sum_{i=1}^{p} \sum_{j=1}^{q} c_{ij}^k x_{ij}, \quad k = 1, 2, ..., K \]  

subject to

\[ \text{Prob} \left( \sum_{j=1}^{q} x_{ij} \leq a_i \right) \geq 1 - \alpha_i, \quad i = 1, 2, ..., p \]  

\[ \text{Prob} \left( \sum_{i=1}^{p} x_{ij} \geq b_j \right) \geq 1 - \beta_j, \quad j = 1, 2, ..., q \]  

\[ 0 \leq x_{ij} \leq r_{ij} \]  

\[ 0 < \alpha_i < 1, \quad 0 < \beta_j < 1. \]  

Here, \( \alpha_i, \beta_j \) are the known confidence levels for the constraints and the TP is unbalanced TP.

3. MATHEMATICAL MODEL INVOLVING CHANCE CONSTRAINED MOCTP (CCMOCCTP)

In various real life CCMOCTPs, three cases may arise (i) only \( a_i \) is random (ii) only \( b_j \) is random (iii) both \( a_i, b_j \) are random. We are interested in developing the model by considering both \( a_i, b_j \) as random. Case (i) and case (ii) are particular cases of case (iii). Here, \( a_i \) and \( b_j \) follow normal distribution with known mean \( E(a_i), E(b_j) \) and variance \( var(a_i), var(b_j) \) respectively. The chance constraints are converted into equivalent deterministic forms by the prescribed mean, variance and confidence levels. The process is described in subsection 3.1.

3.1 Construction of Equivalent Deterministic Constraints

Consider the chance constraints of the form:

\[ \text{Prob} \left( \sum_{j=1}^{q} x_{ij} \leq a_i \right) \geq 1 - \alpha_i, \quad i = 1, 2, ..., p \]

The constraints can be rewritten as:

\[ \frac{\sum_{j=1}^{q} x_{ij} - E(a_i)}{\sqrt{var(a_i)}} \leq \frac{a_i - E(a_i)}{\sqrt{var(a_i)}}, \quad \alpha_i \geq 1 - \text{Prob} \left( \frac{\sum_{j=1}^{q} x_{ij} - E(a_i)}{\sqrt{var(a_i)}} \right) \]

\[ \rightarrow \alpha_i \geq 1 - \text{Prob} \left( \frac{\sum_{j=1}^{q} x_{ij} - E(a_i)}{\sqrt{var(a_i)}} \leq \frac{a_i - E(a_i)}{\sqrt{var(a_i)}} \right) \]

\[ \rightarrow \alpha_i \geq \Phi^{-1} \left( \frac{\sum_{j=1}^{q} x_{ij} - E(a_i)}{\sqrt{var(a_i)}} \right) \]

\[ \rightarrow \Phi^{-1} \left( \alpha_i \right) \geq \frac{a_i - E(a_i)}{\sqrt{var(a_i)}} \]

\[ \rightarrow \Phi^{-1} \left( \alpha_i \right) \sqrt{\text{var(a_i)}} \geq \sum_{j=1}^{q} x_{ij} - E(a_i) \]

\[ \Rightarrow \sum_{j=1}^{q} x_{ij} \leq E(a_i) + \Phi^{-1} \left( \alpha_i \right) \sqrt{\text{var(a_i)}} \quad (6) \]

Here \( \Phi() \) and \( \Phi^{-1}() \) represent the distribution function and inverse of distribution function of standard normal variable respectively.

Now consider \( \text{Prob} \left( \sum_{i=1}^{p} x_{ij} \geq b_j \right) \geq 1 - \beta_j, \quad j = 1, 2, ..., q \).

Then, the constraints can be rewritten as:

\[ \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{var(b_j)}} \geq \frac{b_j - E(b_j)}{\sqrt{var(b_j)}}, \quad \beta_j \geq 1 - \text{Prob} \left( \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{var(b_j)}} \right) \]

\[ \rightarrow \beta_j \geq 1 - \text{Prob} \left( \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{var(b_j)}} \leq \frac{b_j - E(b_j)}{\sqrt{var(b_j)}} \right) \]

\[ \rightarrow \beta_j \geq \Phi \left( \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{var(b_j)}} \right) \]

\[ \rightarrow \Phi^{-1} \left( \beta_j \right) \sqrt{\text{var(b_j)}} \geq \sum_{i=1}^{p} x_{ij} - E(b_j) \]

\[ \Rightarrow \sum_{i=1}^{p} x_{ij} \geq E(b_j) + \Phi^{-1} \left( \beta_j \right) \sqrt{\text{var(b_j)}} \quad (7) \]
\[ \sum_{i=1}^{p} x_{ij} - E(b_j) \]
\[ \Rightarrow \Phi\left( \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{\text{var}(b_j)}} \right) \geq 1 - \beta_j \]
\[ \Rightarrow 1 - \Phi\left( \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{\text{var}(b_j)}} \right) \geq 1 - \beta_j \]
\[ \Rightarrow \Phi\left( \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{\text{var}(b_j)}} \right) \leq \beta_j \]
\[ \Rightarrow \Phi^{-1}(\beta_j) \geq -\frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{\text{var}(b_j)}} \]
\[ \Rightarrow -\Phi^{-1}(\beta_j) \leq \frac{\sum_{i=1}^{p} x_{ij} - E(b_j)}{\sqrt{\text{var}(b_j)}} \]
\[ \Rightarrow \sum_{i=1}^{p} x_{ij} \geq E(b_j) - \Phi^{-1}(\beta_j) \sqrt{\text{var}(b_j)} \tag{7} \]

Then the model reduces to deterministic multi-objective transportation problem as follows:
\[ \min Z^k = \sum_{i=1}^{q} \sum_{j=1}^{k} c_{ij} x_{ij}, \ k = 1, 2, \ldots, K \tag{8} \]
subject to
\[ \sum_{j=1}^{q} x_{ij} \leq E(a_i) + \Phi^{-1}(\alpha_i) \sqrt{\text{var}(a_i)} \tag{9} \]
\[ \sum_{i=1}^{p} x_{ij} \geq E(b_j) - \Phi^{-1}(\beta_j) \sqrt{\text{var}(b_j)} \tag{10} \]
\[ 0 \leq x_{ij} \leq r_{ij}, \ i = 1, 2, \ldots, p \text{ and } j = 1, 2, \ldots, q \tag{11} \]

4. FGP FORMULATION OF CCMOCTP

Generally, the objective function \( Z^k \) represents the TP cost, time, damages during transportation. Our intension is to minimize \( Z^k \) subject to the system constraints (9), (10) and (11). Let the individual best and worst solution of the objective function subject to system constraints be \( Z^k_L \) and \( Z^k_U \) respectively. The fuzzy goals appear as \( Z^k \leq Z^k_L \). The linear membership function for the fuzzy goal can be written as:
\[ \mu_k(Z^k) = \begin{cases} 
1, & \text{if } Z^k \leq Z^k_L \\
\frac{Z^k - Z^k_L}{Z^k_U - Z^k_L}, & \text{if } Z^k_L \leq Z^k \leq Z^k_U, \ k = 1, 2, \ldots, K \\
0, & \text{if } Z^k > Z^k_U 
\end{cases} \tag{12} \]

Here \( (Z^k_U - Z^k_L) \) is the tolerance range for the k-th goal.

Using the model studied by Pramanik and Dey [23] membership goal of each membership function can be written as:
\[ \rho_k(Z^k) = d^k = 1 \]

Here \( d^k \) is the negative deviational variable.

Now, the FGP model for CCMOCTP can be formulated as:
Model Ia:
\[ \min Z^k = \sum_{k=1}^{K} \omega^k d^{-k} \tag{14} \]
subject to \( 1 \geq d^k \geq 0 \) and the constraints (9),(10),(11) and (13).

Model Ib:
\[ \min \lambda \tag{19} \]
subject to the constraints (9), (10), (11), (13) and (15).

Model-II
\[ \min \lambda \tag{19} \]
subject to the constraints \( \lambda \geq d^k \) and (18).

5. SELECTION OF COMPROMISE SOLUTION

In the context of multi-objective decision making, we cannot reach the ideal solution points because of incommensurable objective goals and different conflicting constraints. Decision makers (DMs) try to find out the solution which is closest to the ideal point solution considering all objectives and constraints in the decision making situation. In this connection, several distance functions have been studied [24, 25] to find out the satisfactory solutions. Here, we use the distance function of the type \( s^m = \left\lfloor \frac{K}{k=1} \sum_{k=1}^{K} (1 - \mu^k(Z^k))^m \right\rfloor^{1/m} \) for \( m = 1, 2; k = 1, 2, \ldots, K \).

\[ \mu^k(Z^k) \] is the membership value for the k-th objective function. The solution for which the distance would be the minimum should be taken as the best compromise solution. To identify the FGP model that gives the best satisfactory result, we use the distance function.

6. ILLUSTRATIVE EXAMPLE

To demonstrate the potentiality of the proposed FGP models, we consider the following example. Here, we consider three origins and three destinations. The TP cost, time and the damage charges (both quality and quantity damage) during the transportation are represented by three square matrices of order three. The matrices are given bellow:

\[ \begin{pmatrix} 
3 & 4 & 13 \\
12 & 14 & 7 \\
15 & 10 & 8 
\end{pmatrix} \]

Cost matrix:

\[ \begin{pmatrix} 
9 & 1 & 3 \\
2 & 4 & 6 \\
8 & 12 & 10 
\end{pmatrix} \]

Time matrix:

\[ \begin{pmatrix} 
3 & 4 & 7 \\
2 & 1 & 6 
\end{pmatrix} \]

Damage charge:
Then the objective functions can be represented by
\[ \min Z^1 = (3x_{11} + 4x_{12} + 13x_{13}) + (12x_{21} + 14x_{22} + 7x_{23}) + (15x_{31} + 10x_{32} + 8x_{33}) \]
\[ \min Z^2 = (9x_{11} + x_{12} + 3x_{13}) + (2x_{21} + 4x_{22} + 6x_{23}) + (8x_{31} + 12x_{32} + 10x_{33}) \]
(21)
\[ \min Z^3 = (8x_{11} + 9x_{12} + 11x_{13}) + (3x_{21} + 4x_{22} + 7x_{23}) + (2x_{31} + x_{32} + 6x_{33}) \]
(23)
subject to
\[ \text{Prob} \left( \sum_{j=1}^{3} x_{ij} \leq a_1 \right) \geq 1 - \alpha_1 \]
(24)
\[ \text{Prob} \left( \sum_{j=1}^{3} x_{ij} \leq a_2 \right) \geq 1 - \alpha_2 \]
(25)
\[ \text{Prob} \left( \sum_{j=1}^{3} x_{ij} \leq a_3 \right) \geq 1 - \alpha_3 \]
(26)
\[ \text{Prob} \left( \sum_{i=1}^{3} x_{ij} \geq b_1 \right) \geq 1 - \beta_1 \]
(27)
\[ \text{Prob} \left( \sum_{i=1}^{3} x_{ij} \geq b_2 \right) \geq 1 - \beta_2 \]
(28)
\[ \text{Prob} \left( \sum_{j=1}^{3} x_{ij} \geq b_3 \right) \geq 1 - \beta_3 \]
(29)
The capacitated constraints are given below:
0 \leq x_{11} \leq 6, 0 \leq x_{12} \leq 7, 0 \leq x_{13} \leq 13, 0 \leq x_{21} \leq 6, 
0 \leq x_{22} \leq 2, 0 \leq x_{23} \leq 13, 0 \leq x_{31} \leq 4, 0 \leq x_{32} \leq 7, 
0 \leq x_{33} \leq 14. \quad (30)

The mean, variance and the confidence levels are described below:

Note: Considering the distance functions S₁, S² the solution given by the model (Ib) is the most satisfactory solution.

7. CONCLUSION

This paper presents chance constrained fuzzy goal programming and its application for solving CCMOTP. Two chance constrained FGP models are presented. Distance function is used to obtain the compromise solution. The illustrative example shows that the proposed FGP models offer three different solution set. In general, it cannot be possible to state which FGP model offers better optimal solution. Therefore, it is better to solve the problem by suing the proposed FGP models, and then apply distance function to obtain the most satisfactory solution. Proposed FGP models can also be used in many practical field problems like assignment problems, plant management, planning of resources allocation, travelling salesman problems etc. with random demands and supplies. The concept presented in this paper can also be applied in multi-objective fractional programming problem for non-hierarchical as well as hierarchical organization such as bilevel fractional programming problem, multilevel fractional programming problem with single and multiple objectives.
