ABSTRACT
This paper presents a comparative assessment of modern and intelligent controllers based on time response specification performance for a yaw control of an aircraft system. The dynamic modeling of yaw control system is performed and an autopilot that controls the yaw angle of an aircraft is designed using two controller design methods. The mathematical model of the system is derived by substituting the known parameters of a standard aircraft in standard equations. The transfer function for yaw control surface, i.e. rudder, is derived and two separate controllers, Linear Quadratic Controller (LQR) and Fuzzy Logic Controller (FLC) are designed for controlling the yaw angle. The effectiveness of each controllers are tested and verified using Matlab/Simulink platform. It is found from simulation, LQR controller give the best performance compared to fuzzy logic controller.

General Terms
Fuzzy Logic Controller, LQR Controller, Yaw, Rudder,

Keywords
Aircraft; Flight control, Lateral dynamics; LQR; Fuzzy logic.

1. INTRODUCTION
Today’s aircraft designs rely heavily on automatic control system to monitor and control many of aircraft’s subsystems. The development of automatic control system has played an important role in the growth of civil and military aviation. The architecture of the flight control system, essential for all flight operations, has significantly changed throughout the years. Soon after the first flights, articulated surfaces were introduced for basic control, operated by the pilot through a system of cables and pulleys. This technique survived for decades and is now still used for small airplanes. The introduction of larger airplanes and the increase of flight envelopes made the muscular effort of the pilot, in many conditions, not sufficient to control the aerodynamic moments consequent to the surface deflection. The first solution to this problem was the introduction of aerodynamic balances and tabs, but further grow of the aircraft sizes and flight envelopes brought to the need of powered systems to control the articulated aerodynamic surfaces. Modern aircraft include a variety of automatic control system that aids the flight crew in navigation, flight management and augmenting the stability characteristic of the airplane. The autopilot is an element within the flight control system. Designing an autopilot requires control system theory background and knowledge of stability derivatives at different altitudes and Mach numbers for a given airplane [3]. The number and type of aerodynamic surfaces to be controlled changes with aircraft category. Aircraft have a number of different control surfaces: the primary flight controls, i.e. pitch, roll and yaw control, basically obtained by deflection of elevators, ailerons and rudder (and combinations of them). Yaw is controlled by the rudder. The pilot moves the rudder sideways and the necessary yaw angle is obtained In this paper, the control system design for yaw control is presented. A modern controller (LQR) and intelligent fuzzy logic controller (FLC) is developed for control the yaw of an aircraft system. Performance of both control strategy with respect to the yaw angle and yaw rate is examined. Comparison of both controllers is done and their performance is verified.

2. MODELING OF YAW CONTROL SYSTEM
Two types of dynamical equations are present for an aircraft. The lateral dynamic equations of motion, which represents the dynamics of aircraft with respect to lateral axis and longitudinal dynamic equations of motion which represents the aircraft’s dynamics with respect to longitudinal axis. Lateral dynamics includes yaw, roll and sideslip motions of aircraft. Pitching motion comes under longitudinal dynamics. In this paper, control of yaw angle of aircraft, when it performs yawing motion is explained. The controlsurfaces of aircraft is shown in Fig. 1.

![Figure 1. Yaw, Roll & Pitch motion of Aircraft [10].](image)
The forces, moments and velocity components in the body fixed frame of an aircraft system are shown in Fig. 2 where L, M and N represent the aerodynamic moment components; the term p, q and r represent the angular rates components of roll, pitch and yaw axis and the term u, v and w represent the velocity components of roll, pitch and yaw axis.
The linearized form of the side force, rolling moment and yawing moment equations of motion. In this paper we are taking sideslip angle $\Delta \beta$ instead of the side velocity $\Delta v$. These two quantities are related to each other in the following way:

$$\Delta \beta \approx \tan^{-1} \frac{\Delta v}{u_0} (9)$$

Lateral equations of motion in state space form is shown in equation (10)

$$\begin{bmatrix} \Delta \beta' \\ \Delta p' \\ \Delta r' \\ \Delta \phi' \end{bmatrix} = \begin{bmatrix} Y_g & Y_p & 0 & -1 \\ L_g & L_p & L_r & 0 \\ N_p & N_p & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \Delta \delta_a \\ \Delta \delta_r \end{bmatrix} + \begin{bmatrix} \Delta \delta_p \\ \Delta \delta_r \end{bmatrix}$$

For this system, the input will be the aileron deflection angle and the output will be the pitch angle. In this study, the data from NAVION Transport [1] is used in system analysis and modeling. The lateral directional derivatives stability parameters for this airplane are given in Table I. The values are taken directly from reference [3], as these are standard data of the NAVION aircraft.

| General Aviation
| Airplane: NAVION |
|------------------|------------------|
| Y-Force Derivatives | Yawing Moment Derivatives | Rolling Moment Derivatives |
| Pitching Velocities | $Y_p = 0.254$ | $N_v = 0.025$ | $L_v = -0.091$ |
| Side Slip Angle | $Y_\beta = -44.665$ | $N_\beta = 4.549$ | $L_\beta = -15.969$ |
| Rolling Rate | $Y_r = 0$ | $N_r = -0.349$ | $L_r = -8.395$ |
| Yawing Rate | $Y_\phi = 12.433$ | $N_\phi = -4.613$ | $L_\phi = 23.09$ |
| Rudder Deflection | $Y_\delta = 0$ | $N_\delta = -0.224$ | $L_\delta = -28.916$ |
| Aileron Deflection | $Y_\delta = 0$ | $N_\delta = -0.224$ | $L_\delta = -28.916$ |

The values in the above table is substituted in equation (10). The aileron deflection $\delta a$ in (10) is neglected as we are only concerned about rudder deflection $\delta r$. 

For deriving the lateral equations we assumed that the aircraft is in steady cruise with constant altitude and velocity. Also it is assumed that change in pitch angle does not change the speed of aircraft and the reference flight conditions are symmetric with propulsive forces constant. Therefore,

$$v = p = q = r = \varphi = \psi = 0$$ (1)

$$Y = m g C_y S_y = m \left( \frac{d w}{d t} + r u - p w \right)$$ (2)

$$L = I_x \frac{d \rho}{d t} - I_{xz} \frac{d r}{d t} + q r \left( I_z - I_y \right) - I_{xz} p q$$ (3)

$$N = -I_{xz} \frac{d p}{d t} + I_z \frac{d r}{d t} + p q \left( I_y - I_z \right) - I_{xz} q r$$ (4)

The equations are linearized by replacing all the variables in equations (2),(3) and(4) with a reference value plus a small disturbance. See equation (5)

$$u = u_o + \Delta u \; v = v_o + \Delta v \; w = w_o + \Delta w$$

$$p = p_o + \Delta p \; q = q_o + \Delta q \; Y = y_o + \Delta Y$$

$$r = r_o + \Delta r \; L = L_o + \Delta L \; M = M_o + \Delta M$$

$$\delta = \delta_o + \Delta \delta$$ (5)

Using the above made assumptions, the equations (2),(3) and(4) are linearized. The equations (6),(7) and (8) represents the linearized form, see [1].

$$\left( \frac{d}{d t} - Y_p \right) \Delta v - Y_p \Delta p + \left( u_o - Y_r \right) \Delta r - \left( g \cos \theta_0 \right) \Delta \phi = Y_{dr} \Delta \delta_r$$ (6)

$$-L_p \Delta \rho + \left( \frac{d}{d t} - L_p \right) \Delta \rho - \left( I_{xz} \frac{d}{d t} + L_r \right) \Delta r = L_{\delta a} \Delta \delta_a + L_{dr} \Delta \delta_r$$ (7)

$$-N_r \Delta \rho + \left( \frac{d}{d t} - N_r \right) \Delta \rho - \left( I_{xz} \frac{d}{d t} + N_p \right) \Delta p = N_{\delta a} \Delta \delta_a + N_{dr} \Delta \delta_r$$ (8)
The scaling factor $N$ is computed by equation (12):

$$
\frac{\Delta \phi(s)}{\Delta \delta_r(s)} = \frac{-4.6130 S^3 - 47.9562 S^2 - 118.833 S + 5.7410}{S^4 + 9.4090 S^3 + 14.0189 S^2 + 48.4991 S + 0.3979}
$$

(12)

3. DESIGN PROCESS OF PROPOSED CONTROLLER

Linear Quadratic Regulator (LQR) and Fuzzy Logic Controller (FLC) are proposed for the yaw control system and in this section; these controllers are described in detail.

3.1 Linear Quadratic Regulator (LQR)

Linear quadratic regulator (LQR) is a method in modern control theory and it is an alternative and very powerful method for flight control system designing. The method is based on the manipulation of the equations of motion in state space form and makes full use of the appropriate computational tools in the analytical process [6]. The state and output matrix equations describing the lateral directional equations of motion can be written as the following equation:[3]

$$
\begin{align*}
\dot{x}(t) &= Ax(t) + Bu(t) \\
y(t) &= Cx(t) + Du(t)
\end{align*}
$$

(13)

The feedback gain is a matrix $K$ of the optimal control vector $\beta$.

$$
K = [K_p K_r K_q]
$$

$u(t) = -K x(t) + \Delta \delta_a N
$$

(14)

So as to minimize the performance index,

$$
J = \int_{0}^{T} (x^T Q x + u^T R u) dt
$$

(15)

Where $Q$ is state-cost matrix and $R$ is performance index matrix. For this study, $R=1$ and $Q = C^T C$ where $C$ is the matrix from state equation (13) and $C^T$ is the matrix transpose of $C$. [3] For designing LQR controller, the value of the feedback gain matrix, $K$, must be determined. Matlab is used to determine the values of $K$ by using the lqr command.

The crisp inputs error and change in error are converted to fuzzy membership value on the fuzzy subsets negative big (NB), negative small (NS), zero (ZZ), positive small (PS), positive big (PB) etc.

3.2 Fuzzy Logic Controller (FLC)

The concept of Fuzzy Logic Controller (FLC) was conceived by LotfiZadeh, a professor at the University of California at Berkley, and presented not as a control methodology, but as a way of processing data by allowing partial set membership rather than crisp set membership or non-membership. This approach to set theory was not applied to control systems until the 70’s due to insufficient small-computer capability prior to that time. Professor Zadeh reasoned that people do not require precise, numerical information input, and yet they are capable of highly adaptive control. If feedback controllers could be programmed to accept noisy, imprecise input, they would be much more effective and perhaps easier to implement. In this context, FLC is a problem-solving control system methodology that lends itself to implementation in systems ranging from simple, small, embedded micro-controllers to large, networked, multi-channel PC or workstation-based data acquisition and control systems. It can be implemented in hardware, software, or a combination of both. FLC provides a simple way to arrive at a definite conclusion based upon vague, ambiguous, imprecise, noisy, or missing input information. FLC’s approach to control problems mimics how a person would make decisions, on the basis of intuition, knowledge, and experience. FLC’s approach to set theory is a generalization of classical set theory, and is known as fuzzy set theory. Fuzzy sets are characterized by membership functions that can take on any value between 0 and 1, representing the degree to which an element belongs to a set.

A block diagram of a fuzzy control system is shown in Fig. 3.

An inference mechanism interprets the inputs and take 
decisions to control the plant effectively. A defuzzification 
interface converts the conclusions of the inference 
mechanism into the crisp inputs for the process.

4. APPLICATION AND RESULTS

An aircraft yaw control system is simulated using LQR and 
FLC and the related simulation results are presented and 
discussed. Matlab/Simulink model block diagram of this 
system is shown in Fig. 11. The system response with LQR is 
shown in Fig 8 and that with FLC is shown in fig 9. For 
comparing the performance of the controllers, both the 
responses are plotted on the same graph. in Fig. 10.
From the responses, it is clear that the settling time of FLC is greater than that of LQR controller. LQR controller is faster than FLC, but it has a drawback of overshoot. The steady-state error of LQR controller is very much less than that of FLC, which indicates the disturbance rejection capability of LQR controller. The performance characteristics of both controllers are summarized in Table 3.

5. CONCLUSION
In this paper, the model of an aircraft yaw control system was designed in Matlab/Simulink environment and control methods were proposed for this system. LQR and FLC are successfully designed and responses are verified. The results from LQR are compared with those obtained using FL controller. It was observed that both FLC and LQR have different steady-state error and overshoot. Analysis of obtained results shows that LQR controller relatively gives the best performance in comparison to FLC and using such controller increases speed of the time response and helps in the efficient controlling of the system.
