ABSTRACT
OFDM is a broadband wireless technology which supports data rates in excess of 100 Mbps. In addition to this, OFDM has some limitations as it requires strict frequency synchronization and low peak to average power ratio. So considering DFT-OFDMA, which performance in terms of PAPR, is equivalent to SC-FDMA. This paper represents the suitability of using OFDMA in the up-link for high-data-rate scenarios in local area by considering target performance metrics PAPR. The proposed design shows PAPR performance varies depending on the subcarrier allocation method. It has been also shown that performance of the PAPR by DFT-spreading technique with IFDMA and LFDMA, varying with roll-off factor α of the RC (Raised-Cosine) filter. Effect of the number of subcarriers on PAPR performance is also discussed in this paper.

2. COMPLEMENTARY CUMULATIVE DISTRIBUTION FUNCTION (CCDF)
The CCDF is a parameter to characterize the peak power statistics of a digitally modulated OFDM signal. The CCDF of PAPR information about the percentage of OFDM signals that have PAPR above a particular level. To better approximate the PAPR of a continuous time OFDM signal, the discrete time OFDM signal is to be obtained by L times oversampling. The oversampled discrete time OFDM signal can be obtained by performing L N point IFFT on the data block with (L-1)N zero padding as follows[4]:
\[
x[n]=\frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} x[k] \exp\left[\frac{2\pi j in}{LN}\right] 0 \leq n \leq NL - 1
\]
The probability distribution of complex OFDM signals with large N is a complex Gaussian distribution given by following relation
\[
P_r(x[n]) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left[\frac{-x[n]^2}{2\sigma^2}\right]
\]
where \(Pr(\cdot)\) denotes the probability distribution function. The real and imaginary parts of the complex OFDM signal has Gaussian distribution therefore the magnitude of OFDM signal has Rayleigh distribution. The cumulative distribution function (CDF) of PAPR of an OFDM signal with N subcarriers is given by
\[
\text{CDF } (\gamma_0) = \text{Pr}(\text{PAPR } (x[n]) \leq \gamma_0) = (1 - \exp(-\gamma_0))^N \quad (1.a)
\]
Where \(\gamma_0\) is the threshold value of PAPR. Hence, complementary cumulative distribution function (CCDF) of PAPR becomes CCFD \((\gamma_0) = \text{Pr}(\text{PAPR } (x[n]) > \gamma_0) = (1 - \exp(-\gamma_0))^N\n\]
When oversampling is done by a factor L, the CCDF of OFDM signal (3.20) changes to
\[
\text{CCDF } = (1 - \exp(-\gamma_0))^{LN}
\]
Fig. 1 shows the plots for the CCDF of the OFDM signals for various oversampling factor (L). Here, an OFDM system with QPSK modulation and N=256 subcarrier is assumed in the simulation. It can be easily observed from the Fig. 1, that the PAPR of the discrete-time OFDM signal increases as increase the oversampling factor (L), but for L≥4, the increase in the CCDF of PAPR is very less, hence, an oversampling
factor $L=4$ seems to be adequate for a good estimate of PAPR for a continuous time OFDM signal.

Fig. 1 CCDFs of OFDM signals with $N=64, 128, 256, 512,$ and 1024.

Subcarriers are mutually orthogonal hence overlapping between them is allowed which provide highly spectral efficient system. Despite all these benefits, OFDM faces some drawbacks: sensitivity to Doppler shift, and inefficient power consumption because of high PAPR [5]. Main aim of narrowband subcarrier is to obtain a channel which has almost constant band and also makes less complex equalization at the receiver.

3. PERFORMANCE OF SC-FDMA

SC-FDMA is mainly based on the single-carrier frequency-division multiplexing (SC-FDM) modulation technique. It is also referred as discrete Fourier transform (DFT)-spread OFDM which is also a multiple access scheme. Its main performance is the same as for OFDM; thus, the same benefits are achievable in terms of multipath mitigation as well as less-complexity equalization [6]. But in SCFDMA, DFT is performed before the IFFT block, which spreads the data symbols over all the subcarriers containing information and produces virtual single-carrier structure. As a result, SC-FDM shows lower PAPR than OFDM [7]. This property makes SC-FDM attractive for uplink transmissions, as the user equipment (UE) benefits in terms of transmitted power efficiency. On one hand, all symbols are present in all subcarriers, DFT spreading allows the frequency selectivity of the channel to be exploited.

In OFDM systems, subcarriers are allocated to multiple users. In uplink transmission, each terminal uses a subset of subcarriers to transmit its own data. Rest subcarriers that is not used for its own data transmission, will be filled with zeros. There are two ways of allocating subcarriers among all users: DFDM (Distributed FDMA) and LFDM (Localized FDMA). Here, DFDM distributes M DFT outputs over the entire band (of total N subcarriers) with zeros filled in (N-M) unused subcarriers and Localized FDMA allocates DFT outputs to all M consecutive subcarriers in N number of subcarriers. When DFDM distributes DFT output with equal distance (N/M=S) it is known as IFDMA (Interleaved FDMA) where S is bandwidth spreading factor. It will assume that the number of subcarriers allocated to each user is M. In the DFT-spreading technique, M-point DFT is used for spreading, and the output of DFT is assigned to the subcarriers of IFFT. The effect of PAPR reduction depends on the way of assigning the subcarriers to each terminal [8].

DFT Spreading for IFDMA, DFDM and LFDM: 3 users with $N=12, M=4$ and $S=3$

$N=SM \{ \tilde{X}[k]_{IFDMA} \}$

$12=3.4$

$N > SM \{ \tilde{X}[k]_{DFDMA} \}$

$12=3.4$

$N=SM \{ \tilde{X}[k]_{LFDMA} \}$

$12=3.4$

uplink transmitter with the DFT-spreading technique that employs IFDMA. Here, the input data $x[m]$ is DFT-spread to generate $X[i]$ and then, allocated as

$$\tilde{X}(k) = \begin{cases} X[\frac{k}{S}], & k = 5.m1, m1 = 0, 1, 2, \ldots, N-1 \\ 0, & \text{otherwise} \end{cases}$$

The IFFT $\hat{x}[n]$ with $n=M.s+m$ for $s=0, 1, 2, \ldots, S-1$ and $m=0, 1, 2, \ldots, M-1$

$$\hat{x}[n] = \frac{1}{N} \sum_{k=0}^{N-1} X[k] \exp\left(\frac{2\pi \text{i} mn}{N}\right)$$

Put the value of $n$ in (2.1)-

$$= \frac{1}{S} x[m]$$

Which turns out to be a repetition of the original input signal $x[m]$ scaled by $1/S$ in the time domain. In the IFDMA where the subcarrier mapping starts with the rth subcarrier ($r = 0, 1, 2, \ldots, S-1$) the DFT spread symbol can be expressed as

$$\tilde{X}(k) = \begin{cases} X[\frac{k-r}{S}], & k = 5.m1 + r, m1 = 0, 1, 2, \ldots, N-1 \\ 0, & \text{otherwise} \end{cases}$$

Then, the corresponding IFFT output sequence $\hat{x}[n]$ is given by
\[ \hat{x}[n] = \hat{x}(MS + m) \]
\[ = \frac{1}{N} \sum_{k=0}^{N-1} \hat{x}[k] \exp\left(\frac{j2\pi kn}{N}\right) \]
\[ = \frac{1}{N} \sum_{k=0}^{N-1} x[m] \exp\left(\frac{j2\pi kn}{N}\right) \]
\[ \hat{x}[m], \exp\left(\frac{j2\pi r}{N}\right) \quad (2.2) \]

Compared with (2.1), one can see that the frequency shift of subcarrier allocation starting point by \( r \) subcarriers results in the phase rotation of \( e^{j2\pi r/N} \) in IFDMA.

In the DFT-spreading scheme for LFDMAs, the IFFT input signal \( \hat{X}(k) \) at the transmitter can be expressed as

\[ \hat{x}(k) = \begin{cases} x[k], & k = 0, 1, 2, \ldots, M - 1 \\ 0, & k = M, M + 1, \ldots, N - 1 \end{cases} \]

Then, the corresponding IFFT output sequence

\[ \hat{x}[n] = \hat{x}(Ms + m) \frac{1}{N} \sum_{k=0}^{N-1} \hat{x}[k] \exp\left(\frac{j2\pi kn}{M}\right) \]
\[ = \frac{1}{N} \sum_{k=0}^{M-1} x[m] \exp\left(\frac{j2\pi k}{M}\right) \]
\[ = \frac{1}{N} \sum_{k=0}^{M-1} x[m] \exp\left(\frac{j2\pi k}{M}\right) \quad (2.3) \]

For \( s = 0 \),

\[ X[k] = \hat{x}[Sm] \]
\[ = \frac{1}{N} \sum_{k=0}^{M-1} x[m] \exp\left(\frac{j2\pi k}{M}\right) \]
\[ = \frac{1}{N} \sum_{k=0}^{M-1} x[m] \exp\left(\frac{j2\pi k}{M}\right) \]
\[ = \frac{1}{N} \sum_{k=0}^{M-1} x[m] \exp\left(\frac{j2\pi k}{M}\right) \quad (2.4) \]

From (2.3) and (2.4), LFDMAs signal becomes the \( 1/S \)-scaled copies of the input sequence at the multiples of \( S \) in the time domain. The values in-between are obtained by summing all the input sequences with the different complex-weight factor.

**4. SIMULATION AND RESULTS**

Fig.2 shows a comparison of PAPR performances when the DFT-spreading technique is applied to the IFDMA, LFDMAs, and OFDMA. Here, 4-QAM, 16-QAM, and 64-QAM are used for an SC-FDMA system with \( N=256 \), \( M=64 \), and \( s=4 \). It can be seen from Fig. 2 that the PAPR performance of the DFT-spreading technique varies depending on the subcarrier allocation method. In the case of 16-QAM, the values of PAPRs with IFDMA, LFDMAs, and OFDMA for CCDF of 1% are 3.5dB, 8.3dB, and 10.8dB, respectively. It implies that the PAPRs of IFDMA and LFDMAs are lower by 7.3dB and 3.2dB, respectively, than that of OFDMA with no DFT spreading.
4.1 Effect of pulse shaping

In DFT-spreading scheme, PAPR performance is affected by pulse shaping. Figure 5 shows the PAPR graph of DFT-spreading technique with IFDMA and LFDMA, varying independently with the roll-off factor $\alpha$ of the RC (Raised-Cosine) filter for pulse shaping after the IFFT block. It has been observed from this figure that the PAPR graph of IFDMA can be significantly improved by increasing the roll-off factor from $\alpha = 0$ to $1$ whereas in LFDMA, PAPR is not so much affected by pulse shaping. It conclude that IFDMA will have a trade-off between excess bandwidth and PAPR graph since excess bandwidth increases as the roll-off factor becomes larger. Figure 3 shows the results with the simulation parameters of $N=256, M=64, S=4$ (spreading factor), and $N_o=8$ (oversampling factor for pulse shaping) for both QPSK and 16-QAM.

4.2 Effect of number of Subcarrier M:

The PAPR graph of DFT-spreading technique is affected by changing the number of subcarriers, $M$. Fig.4 shows that the PAPR graph of DFT-spreading technique for Localized FDMA with a roll-off factor of $\alpha =0.4$ is degraded as $M$ increases, for example $M= N_o=4$ to 128. Here, 64-QAM is used for the SC-FDMA system with 256-point FFT ($N=256$).

5. CONCLUSION

In conclusion, the PAPRs of LFDMA and IFDMA are lower by 3.2dB and 7.3dB, respectively, than that of OFDMA of no DFT spreading. Results shows that, the SC-FDMA systems consisting of IFDMA and LFDMA have a better performance of PAPR than OFDMA systems. Because of the fact that subcarriers allocation over the entire band (IFDMA) is not easy to implement and requires the additional resources such as guard band and pilots, hence LFDMA is preferred for implementation although IFDMA shows lower PAPR in above results.
