ABSTRACT

Increased data rates and reliability are the two key factors required to support emerging multimedia applications and new communications technologies. The two techniques used in high data rate transmission are orthogonal frequency division multiplexing (OFDM) and multiple-input multiple-output (MIMO) scheme. The OFDM is used to mitigate the problem of inter symbol interference (ISI) and provides good protection against co-channel interference and noise. MIMO system helps to reduce fading and can be used for decreasing bit error rate that is spatial diversity or to increase the data rate that is spatial multiplexing. The combination of MIMO and OFDM is MIMO OFDM system. MIMO-OFDM system converts frequency selective MIMO channel into multiple parallel flat fading channels. One of the major drawbacks of in MIMO-OFDM systems is that the transmitted signal exhibits a high PAPR when the input sequences are correlated. In this paper, AMS and PTS schemes have been used to reduce peak to average power ratio (PAPR) in multiple input multiple output orthogonal frequency division multiplexing (MIMO OFDM) system with Alamouti’s space time block coding (STBC). The AMS scheme reduces the computational complexity and when AMS scheme is used with quadrature amplitude modulation (QAM). Simulation and results show that the AMS scheme reduces PAPR more efficiently than the PTS scheme.

1. INTRODUCTION

With the advent of next generation (4G) broadband wireless communications, the combination of multiple-input multiple-output (MIMO) wireless technology with orthogonal frequency division multiplexing (OFDM) has been recognized as one of the most promising techniques to support high data rate and high performance [1]. Multiple-input multiple-output (MIMO) wireless technology in combination with orthogonal frequency division multiplexing (OFDM) is an attractive air interface solution for next-generation wireless local area networks (WLANs), wireless metropolitan area networks (WMANs), and fourth-generation mobile cellular wireless systems [2]. Multiple-input multiple-output (MIMO) technology meet the demands of next generation by offering increased spectral efficiency through spatial multiplexing gain, and improved link reliability due to antenna diversity gain [3]. OFDM has the potential to play an important role in the design of the next generation broadband wireless communication systems. Orthogonal frequency division multiplexing (OFDM) is a multi-carrier modulation technique that transmits the signals through multiple carriers and these multi-carriers or subcarriers have different frequencies. The major advantage of OFDM is its ability to cope with severe channel conditions, for example, multipath fading and narrowband interference, without complicated equalization filters [1]. One popular combination of MIMO and OFDM is the STBC-OFDM which was first proposed in [4, 5]. Alamouti-based space-time coding technique is one of the most effective transmitter diversity methods and when combined with OFDM, it enhances the system performance [6]. Space-time block coding (STBC) has come out as one of the major techniques to tap the MIMO benefit. STBC consists of data coded through space and time to improve the reliability of the transmission. An OFDM signal has high PAPR from the summation of the subcarriers at the transmitter and some combination of the subcarriers creates large peaks. The envelope of the transmitted signal is not constant showing peaks whose power exceeds the mean power. Therefore, to prevent the OFDM signal from distortion, the transmit amplifier must work in linear region. Therefore, for OFDM systems large range power amplifiers are required. But these amplifiers increase the cost of the OFDM systems. Consequently, reducing the PAPR is essential to reduce the cost of OFDM systems. Recently, various algorithms of the PAPR reduction have been proposed for MIMO OFDM systems in the literature, including clipping [7], selected mapping (SLM) [8], [9], partial transmit sequences (PTS) [10], [11]. However, when these methods are directly employed to reduce the PAPR in MIMO-OFDM systems, it results in an increase of the complexity and redundancy with the increasing number of antennas.

In this paper, an alternative multisequence (AMS) [12] and partial transmit sequence (PTS) scheme is used to reduce the PAPR of MIMO-OFDM signals. Alamouti space–time block coding (STBC) is employed in MIMO-OFDM systems in this paper with 4-QAM and 16-QAM.

2. SYSTEM MODEL

In this MIMO OFDM system, STBC codes are used as a channel coding technique to do error correction and detection and AMS/PTS scheme is employed to reduce PAPR. The input bits are given to modulator where modulation of input bits takes place using M-QAM complex constellation.

The modulated signal is given by

\[ S_m(t) = A_{m_2}g(t) \cos(2\pi f_c t) - A_{m_2}g(t) \sin(2\pi f_c t) \quad .... (1) \]
are information bearing signal amplitudes of quadrature carriers and \( g(t) \) is the input signal pulse.

The M-QAM modulated symbols are passed through the STBC encoder and complex matrix \( Z \) is generated such that symbols are coded through space and time. So, replicas of modulated symbols for Alamouti coding are sent through two transmit antennas and over two time slots.

The encoded sequence can be found by

\[
Z = \begin{bmatrix} z_0 - z_1^* \\ z_1 + z_0^* \end{bmatrix} \quad \ldots \ldots (2)
\]

The encoded bits are given to the OFDM modulator where the bits are mapped with the orthogonal carriers. An inverse FFT is computed on each set of symbols, giving a set of complex time-domain samples.

\[
z(n) = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} Z(k) e^{-j2\pi kn/N} \quad \ldots \ldots (3)
\]

where \( j = \sqrt{-1} \) and \( n = 0, 1, \ldots, (N-1) \).

After OFDM modulation, AMS or PTS scheme is applied to reduce PAPR. Finally, the signal with minimum PAPR is transmitted through its respective antennas.

The PAPR of MIMO-OFDM system is defined by

\[
\text{PAPR}(z(n)) = \frac{\max \{|z(n)|^2\}}{E\{|z(n)|^2\}} \quad \ldots \ldots (4)
\]

where \( E\{\cdot\} \) is the mathematical expectation.

Complementary cumulative density function (CCDF) for PAPR is given by

\[
\text{CCDF}(\text{PAPR}(z(n))) = P_e(\text{PAPR}(z(n)) < \text{PAPR}_0) \quad \ldots \ldots (5)
\]

### 3. METHODS

#### 3.1 AMS Scheme

The AMS scheme is proposed by Tao Jiang and Cai Li in 2012 [12]. In this scheme, after STBC encoder, the coded data is partitioned into sub blocks, and IFFT operation is performed on each sub block where the frequency domain signals are converted into time domain signals.

Finally, AMS scheme is implemented, in which two inputs are given to the AMS block one input is from IFFT block and another input to AMS block is the conjugate of the output of the IFFT block. The input of the IFFT block is \( y_i^m, (m = 0, 1, \ldots, M-1) \), then the two inputs to the AMS block will be \( t_i^m \) and \( t_i^m \) where,

\[
t_i^m = (t_i^m)^* \quad \ldots \ldots (6)
\]

The AMS scheme will generate new sequences which are given by

\[
t_i^m = a^m(t_i^m)^* + b^m t_i^m \quad \ldots \ldots (7)
\]

\[
t_i^m = a^m(t_i^m)^* - b^m t_i^m \quad \ldots \ldots (8)
\]

where \( a^m \) and \( b^m \) are positive integers with \( a^m \neq 0 \) and \( c^m = 1 \) and 2 respectively. Then the alternate transmitted signals are given by

\[
t_i = \sum_{m=0}^{M-1} t_i^m \quad \ldots \ldots (9)
\]

where \( i = 1, 2 \).

Finally, the signal with the lowest PAPR are chosen for transmission.

#### 3.2 PTS Scheme

The partial transmit sequence (PTS) is an attractive technique because of good PAPR reduction performance and no restriction to the number of subcarriers [13]. It can be said that PTS method is a modified method of SLM. PTS method works better than SLM method. The main advantage of this scheme is that there is no need to send any side information to the receiver of the system, when, differential modulation is applied in all sub blocks. In this scheme, the coming input bits are divided into smaller disjoint sub blocks. Input from each partitioned sub block converted from frequency domain to time domain by using \( N \)-point inverse fast fourier transform (IFFT). The time domain sequences are multiplied by rotating phase factors, \( z = [x_1, x_2, \ldots, x_M]^T \), to minimize PAPR and then these sequences are then added to form the OFDM symbol for transmission.

The resulting time domain signal,

\[
x'(z) = \sum_{m=1}^{M} z_m x_m \quad \ldots \ldots (10)
\]

Allowable phase factor,

\[
x_m = e^{j\Phi_m} \quad \ldots \ldots (11)
\]

\( x_m \) is the time domain sequence and \( \Phi_m \) can take the value between \( (0, 2\pi) \).

The main aim of this scheme is to design an optimal phase factor for each sub block set that minimizes the PAPR. Finally, the signal with the lowest PAPR are chosen for transmission.

### 4. SIMULATION AND RESULTS

Simulations have been conducted to evaluate the PAPR reduction in STBC MIMO OFDM system where number of subcarriers, \( N=256 \), oversampling factor, \( N_{os}=4 \), number of subblocks, \( M = 2 \) & 4, and number of OFDM blocks for iteration, \( N_{blk} = \) 3000. Complementary cumulative density function is used to depict the statistical properties of PAPR in STBC MIMO OFDM system, as PAPR is a random variable.
Figure 2, figure 3, figure 4, figure 5, figure 6 and figure 7 show the reduction of PAPR with AMS/PTS with $M=2$ and 4, and original signal for 4-QAM, 8-QAM, 16-QAM, 32-QAM, 64-QAM and 128-QAM. In this PTS scheme is applied with the number of phase rotation factors for each subblock, i.e. $W$ is equal to the number of subblocks, which means for $M=2$, $W=2$ and for $M=4$, $W=4$, respectively. Table I shows the different values of PAPR at $P_r(\text{PAPR}>\text{PAPR}_0) = 10^{-2}$. For 4-QAM, when the original signal is compared with the AMS
scheme, 1.5097 dB and 2.7621 dB PAPR reduction with M=2 and M=4, whereas when the original signal is compared with the PTS scheme, 0.545 dB and 2.1871 dB PAPR reduction with M=2 and M=4. For 8-QAM, when the original signal is compared with the AMS scheme, 1.2346 dB and 2.6646 dB PAPR reduction with M=2 and M=4, whereas when the original signal is compared with the PTS scheme, 0.53 dB and 2.1093 dB PAPR reduction with M=2 and M=4.

For 16-QAM, when the original signal is compared with the AMS scheme, 1.3339 dB and 2.7495 dB PAPR reduction with M=2 and M=4, whereas when the original signal is compared with the PTS scheme, 0.55 dB and 2.11 dB PAPR reduction with M=2 and M=4. For 32-QAM, when the original signal is compared with the AMS scheme, 1.5537 dB and 2.8212 dB PAPR reduction with M=2 and M=4, whereas when the original signal is compared with the PTS scheme, 0.628 dB and 2.1395 dB PAPR reduction with M=2 and M=4. For 64-QAM, when the original signal is compared with the AMS scheme, 1.5232 dB and 2.842 dB PAPR reduction with M=2 and M=4, whereas when the original signal is compared with the PTS scheme, 0.672 dB and 2.254 dB PAPR reduction with M=2 and M=4. For 128-QAM, when the original signal is compared with the AMS scheme, 1.254 dB and 2.5861 dB PAPR reduction with M=2 and M=4, whereas when the original signal is compared with the PTS scheme, 0.569 dB and 2.054 dB PAPR reduction with M=2 and M=4.

5. CONCLUSION

Orthogonal frequency division multiplexing (OFDM) is a very attractive technique for wireless communications due to its spectrum efficiency and channel robustness. One of the major drawbacks of in MIMO-OFDM systems is that the transmitted signal exhibits a high PAPR when the input sequences are correlated. In the present work, two different PAPR reduction techniques i.e. AMS and PTS have been implemented on the MIMO OFDM system and the PAPR reduction parameter has been analyzed. The Alamouti’s STBC has been used to make MIMO OFDM system. The results show that AMS scheme is more effective than the PTS scheme to reduce PAPR in STBC MIMO OFDM systems with QAM modulation.

6. FUTURE SCOPE

Further this work can be extended to increase the performance of the MIMO-OFDM system by using different channel coding techniques and using other PAPR reduction techniques. Also there is a scope to implement the MIMO-OFDM system by using different modulation schemes.
