## ABSTRACT

Let  $G = (V, E)$  be a connected simple graph. For any non-trivial additive abelian group  $A$ , let  $A^* = A - \{0\}$ . A function  $f: E(G) \rightarrow A^*$  is called a labeling of  $G$ . Any such labeling induces a map  $f^+ : V(G) \rightarrow A$ , defined by  $f^+(v) = \sum f(uv)$ , where the sum is over all  $uv \in E(G)$ . If there exist a labeling  $f$  whose induced map on  $V(G)$  is a constant map, we say that  $f$  is an  $A$ -magic labeling of  $G$  and that  $G$  is an  $A$ -magic graph. In this paper we obtained the group magic labeling of cycles with a common vertex, a chain of three cycles and even number of times even cycles in a chain.

## Key words

$A$ -magic labeling, Group magic, cycles with a common vertex, chain of cycles.

## 1. INTRODUCTION

Labeling of graphs is a special area in Graph Theory. A detailed study has been done in [1]. Originally Sedlacek has defined magic graph as a graph whose edges are labeled with distinct non-negative integers such that the sum of the labels of the edges incident to a particular vertex is the same for all vertices. If those labels are from a non trivial additive abelian group  $A$ , then graph is said to be Group magic graph or  $A$ -magic.  $A$ -magic graph is introduced by J sedlacek. Recently  $A$ -magic graphs are studied and investigated in the literature [2,3,4,5,6].

An  $A$ -magic graph  $G$  is said to be  $Z_k$ -magic graph if we choose the group  $A$  as  $Z_k$ - the group of integers mod  $k$ . These  $Z_k$ -magic graphs are referred as  $k$ -magic graphs. Baskar Babujee, L.Shobana [7] have shown few graphs like cycle graphs, complete, bistar, ladder, etc. are  $Z_3$ -magic. A detail study about zero-sum magic graphs and their null sets was done by Ebrahim salehi in [8].

It was proved in [9] that wheels, fans, cycles with a  $P_k$  chord, books are group magic. In [10] it was proved that wheels can be labeled with at most  $n$  distinct labels, where  $n$  is the number of vertices. In [11] the graph  $B(n_1, n_2, \dots, n_k)$ , the  $k$  copies of  $C_{n_j}$  with a common edge or path is labeled. In [12] a biregular graph is defined and group magic labeling of few biregular graphs have been dealt with. In [13] the group magic labeling of two or more cycles with a common vertex is derived. As an extension of this result in this paper the group magic labeling of a chain of three cycles and even number of times even cycles in a chain are considered.

## 2. DEFINITIONS

2.1 Let  $G = (V, E)$  be a connected simple graph. For any non-trivial additive abelian group  $A$ , let  $A^* = A - \{0\}$ . A function  $f: E(G) \rightarrow A^*$  is called a labeling of  $G$ . Any such labeling induces a map  $f^+ : V(G) \rightarrow A$ , defined by  $f^+(v) = \sum_{uv \in E(G)} f(u,v)$  If there exists a labeling  $f$  which

induces a constant label  $c$  on  $V(G)$ , we say that  $f$  is an  $A$ -magic labeling and that  $G$  is an  $A$ -magic graph with index  $c$ .

- 2.2 A  $A$ -magic graph  $G$  is said to be  $Z_k$ -magic graph if we choose the group  $A$  as  $Z_k$ - the group of integers mod  $k$ . These  $Z_k$ -magic graphs are referred as  $k$ -magic graphs.
- 2.3 A graph  $G = (V; E)$  is called fully magic if it is  $A$ -magic for every abelian group  $A$ . For example, every regular graph is fully magic.
- 2.4 A graph  $G = (V,E)$  is called non-magic if for every abelian group  $A$ ; the graph is not  $A$ -magic.  
  
The most obvious class of non-magic graphs is  $P_n$  ( $n \geq 3$ ); the path of order  $n$ . As a result, any graph with a pendant path of length  $n \geq 3$  would be non-magic [7].
- 2.5 A  $k$ -magic graph  $G$  is said to be  $k$ -zero-sum (or just zero sum) if there is a magic labeling of  $G$  in  $Z_k$  that induces a vertex labeling with sum zero.
- 2.6  $B_V(n_1, n_2, \dots, n_k)$  denotes the graph with  $k$  cycles  $C_j$  ( $j \geq 3$ ) of size  $n_j$  in which all  $C_j$ 's ( $j=1,2,\dots,k$ ) have a common vertex.
- 2.7 The chain of cycles  $C(n_1, n_2, \dots, n_k)$  denotes the graph of  $k$  cycles  $C_1, C_2, \dots, C_k$  of sizes  $n_1, n_2, \dots, n_k$  such that for  $i=1,2,\dots,k-1$ ,  $C_i$  and  $C_{i+1}$  have a common vertex.

## 3. OBSERVATION [1]

By labeling the edges of even cycle as  $\alpha$ , the vertex sum is  $2\alpha$  or if their edges are labeled as  $\alpha_1$  &  $\alpha_2$  alternatively then the vertex sum is  $\alpha_1 + \alpha_2$ . But the edges of odd cycles can only be labeled as  $\alpha$  with the index sum  $2\alpha$ .

## 4. MAIN RESULTS

### 4.1 Theorem

The graph of two cycles  $C_1$  and  $C_2$  with a common vertex is group magic when both cycles are either odd or even.

Proof:

$G$  is the graph of 2 cycles  $C_1$  and  $C_2$  with a common vertex. Let  $u$  be the common vertex. The vertices which are adjacent with  $u$  of the two cycles  $C_1$  and  $C_2$  be  $u_1, v_1$  and  $u_2, v_2$  respectively. If the edges  $uu_1, uv_1, uu_2$ , and  $uv_2$  are labeled as  $\alpha_1, \alpha_2, \alpha_3$  &  $\alpha_4$ , the  $\alpha$ 's are chosen from  $A^*$  such that the edge labels are nonzero, then the vertex sum at  $u$  is  $\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4$ . To get this vertex sum at each of the other vertices we have to label the edges of cycle  $C_1$  as  $\alpha_2 + \alpha_3 + \alpha_4$  and  $\alpha_1$  alternatively from the edge which is adjacent with  $u_1$ . Similarly the edges of the cycle  $C_2$  are labeled as  $\alpha_1 + \alpha_2 + \alpha_4$  and  $\alpha_3$  alternatively from the edge which is adjacent with  $u_2$ . This labeling gives the vertex sum as  $\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4$  at all vertices except at  $v_1$  and  $v_2$ .

Fig 1

Case 1: Both  $C_1$  and  $C_2$  are odd cycles.

If  $C_1$  and  $C_2$  are odd cycles the edge which is adjacent with  $uv_1$  gets the label as  $\alpha_2+\alpha_3+\alpha_4$  and the edge which is incident with  $uv_2$  gets the label as  $\alpha_1+\alpha_2+\alpha_4$ . So at  $v_1$  and  $v_2$  the magic condition requires

$$\alpha_2+\alpha_3+\alpha_4+\alpha_2 = \alpha_1+\alpha_2+\alpha_3+\alpha_4$$

$$\alpha_1+\alpha_2+\alpha_4+\alpha_4 = \alpha_1+\alpha_2+\alpha_3+\alpha_4$$

Hence  $\alpha_1=\alpha_2$ , and  $\alpha_3=\alpha_4$ .

Thus when the cycles  $C_1$  and  $C_2$  are odd, the edges incident with  $u$  of  $C_i$  ( $i=1,2$ ) are labeled as  $\alpha_i$  ( $i=1,2$ ) the remaining edges of  $C_1$  are labeled as  $\alpha_1+2\alpha_2$  and  $\alpha_1$  alternatively while those of  $C_2$  labeled as  $2\alpha_1+\alpha_2$  and  $\alpha_2$  alternatively. This labeling gives the vertex sum  $2(\alpha_1+\alpha_2)$ .

Fig 2

Case 2: Both  $C_1$  and  $C_2$  are even

If  $C_1$  and  $C_2$  are even cycles the edge which is adjacent with  $uv_1$  gets the label as  $\alpha_1$  and the edge which is adjacent with  $uv_2$  gets the label as  $\alpha_3$ . So at  $v_1$  and  $v_2$  the magic condition requires

$$\alpha_1+\alpha_2 = \alpha_1+\alpha_2+\alpha_3+\alpha_4$$

$$\alpha_3+\alpha_4 = \alpha_1+\alpha_2+\alpha_3+\alpha_4$$

Hence  $\alpha_1+\alpha_2=0$ , and  $\alpha_3+\alpha_4=0$

This leads to the vertex sum as zero.

Hence when the cycles  $C_1$  and  $C_2$  are even, by the above discussion  $G$  is zero sum magic.

Case 3: Either  $C_1$  or  $C_2$  is odd

Suppose  $C_1$  is odd and  $C_2$  is even, the edge which is adjacent with  $uv_1$  gets the label as  $\alpha_2+\alpha_3+\alpha_4$  and the edge which is adjacent with  $uv_2$  gets the label as  $\alpha_3$ .

So at  $v_1$  and  $v_2$  the magic condition requires

$$\alpha_2+\alpha_3+\alpha_4+\alpha_2 = \alpha_1+\alpha_2+\alpha_3+\alpha_4$$

$$\alpha_3+\alpha_4 = \alpha_1+\alpha_2+\alpha_3+\alpha_4$$

Hence  $\alpha_1=\alpha_2$ , and  $\alpha_1+\alpha_2=0$ .

Which in turn  $\alpha_1=0$  which is impossible.  $\square$

This result can be extended to  $B_V(n_1, n_2, \dots, n_k)$ .

## 4.2 Theorem

$B_V(n_1, n_2, \dots, n_k)$  for  $k \geq 3$  is group magic.

Proof :

Denote the common vertex in  $B_V(n_1, n_2, \dots, n_k)$  as  $u$  and the vertices of  $C_j$  which are adjacent to  $u$  as  $u_j$  and  $v_j$  for every  $j = 1, 2, \dots, k$ .

Case 1: Among  $C_j$ 's ( $j=1, 2, \dots, k$ ) at least two are even cycles.

For our convenience let us take  $C_1, C_2, \dots, C_s$  are the odd cycles and the remaining  $k-s$  cycles are even. In each  $C_j$ , label the edges  $uu_j$  and  $uv_j$  as  $\alpha_{2j-1}$  and  $\alpha_{2j}$ . At  $u$  the vertex sum is  $\sum_{i=1}^{2k} \alpha_i$ . Choose  $\alpha$ 's from  $A^*$  such that the edge labels are nonzero.

In  $C_1$  the remaining edges are labeled  $\sum_{i=1}^{2k} \alpha_i - \alpha_1$  and  $\alpha_1$  alternatively from the edge which is incident with  $u_1$ . At  $v_1$  the magic condition requires

$$\sum_{i=1}^{2k} \alpha_i - \alpha_1 + \alpha_2 = \sum_{i=1}^{2k} \alpha_i$$

That is  $\alpha_1 = \alpha_2$

Similarly we can do for the cycles  $C_j$  for  $j=2, \dots, s$ .

we have  $\alpha_{2j-1} = \alpha_{2j}$  for  $j=2, \dots, s$ .

In each  $C_j$  for  $j = s+1, s+2, \dots, k$ , the remaining edges are labeled  $\sum_{i=1}^{2k} \alpha_i - \alpha_{2j-1}$  and  $\alpha_{2j-1}$  alternatively from the edge which is incident with  $u_j$ . At  $v_j$  the magic condition requires

$$\alpha_{2j-1} + \alpha_{2j} = \sum_{i=1}^{2k} \alpha_i$$

That is  $\sum_{i=1, i \neq 2j-1, i \neq 2j}^{2k} \alpha_i = 0$  for each  $j = s+1, s+2, \dots, k$

These  $k-s$  equations can be written as,

$$2 \sum_{i=1}^s \alpha_{2i-1} + \sum_{i=s+1, i \neq j}^k (\alpha_{2i-1} + \alpha_{2i}) = 0 \quad (1)$$

Taking  $M = -2 \sum_{i=1}^s \alpha_{2i-1}$

Equation (1) gives

$$\sum_{i=s+1, i \neq j}^k (\alpha_{2i-1} + \alpha_{2i}) = M$$

From these  $k-s$  equations we get  $\alpha_{2j-1} + \alpha_{2j} = \alpha_{2i-1} + \alpha_{2i}$  for every  $i$  and  $j = s+1, s+2, \dots, k$ .

Substituting in (1) we get for each  $j = s+1, s+2, \dots, k$

$$2 \sum_{i=1}^s \alpha_{2i-1} + (k-s-1)(\alpha_{2j-1} + \alpha_{2j}) = 0$$

$$\text{That is } \alpha_{2j-1} + \alpha_{2j} = \frac{1}{k-s-1} M \quad (2)$$

Provided  $k-s \neq 1$ , that is  $B_V(n_1, n_2, \dots, n_k)$  contains at least two even cycles.

Thus choosing  $\alpha_j$  for  $j = s+1, s+2, \dots, k$  in such a way that it satisfies (2) will give the group magic labeling with the vertex sum

$$\begin{aligned} \sum_{i=1}^{2k} \alpha_i &= -M + (k-s)(\alpha_{2j-1} + \alpha_{2j}) \\ &= -M + \frac{k-s}{k-s-1} M \\ &= \frac{1}{k-s-1} M \end{aligned} \quad (3)$$

If all the cycles are even then  $M$  takes the value zero. So  $B_V(n_1, n_2, \dots, n_k)$  is zero sum magic when all  $n$ 's are even.

Case 2: Among  $C_j$ 's ( $j=1, 2, \dots, k$ ) only one  $C_j$  is even cycle.

Let  $C_k$  be the even cycle. Label the edges  $uu_j$  and  $uv_j$  as  $\alpha_j$  ( $j=1, 2, \dots, k-1$ ) and the remaining edges of those  $C_j$ 's are labeled  $T-\alpha_j$  and  $\alpha_j$  alternatively, where  $T$  is the vertex sum.

Label the edges  $uu_k$  and  $uv_k$  as  $\alpha_k$  and  $\alpha_k$ . Here the vertex sum is

$$T = 2 \sum_{i=1}^{k-1} \alpha_i + \alpha_k + \alpha_k$$

Since  $C_k$  is even cycle, the remaining edges of  $C_k$  are labeled as  $T-\alpha_k$  and  $\alpha_k$  alternatively from the edge which is incident with  $u_k$ . At  $v_k$  the magic condition requires

$$\alpha_k + \alpha_{k'} = 2 \sum_{i=1}^{k-1} \alpha_i + \alpha_k + \alpha_{k'}$$

Shows  $\sum_{i=1}^{k-1} \alpha_i = 0$  (4)

Thus choosing  $\alpha_j$  for  $j = 1, 2, \dots, k-1$  in such a way that it satisfies (4) will give the group magic labeling with the vertex sum  $T = \alpha_k + \alpha_{k'}$ . Here  $k > 2$ . If  $k=2$  the condition (4) shows  $\alpha_1 = 0$  which is impossible. This one is derived in case 3 of theorem 4.1.

**Case 3:** All  $C_j$ 's ( $j=1, 2, \dots, k$ ) are odd.

Label the edges  $uu_j$  and  $uv_j$  as  $\alpha_j$  ( $j=1, 2, \dots, k$ ) and the remaining edges of  $C_j$  are labeled alternatively as  $2 \sum_{i=1}^k \alpha_i - \alpha_j$  and  $\alpha_j$ . This labeling induces a vertex sum  $2 \sum_{i=1}^k \alpha_i$ . □

### 4.3 Illustrations

For case 1

Consider  $k=4$  and  $s=2$  and choose the edge labels  $\alpha_1 = \alpha_2 = 1$ ,  $\alpha_3 = \alpha_4 = 2$ , then  $M = -2(1+2) = -6$  and  $k-s-1 = 1$

Now choose  $\alpha_5, \alpha_6, \alpha_7$ , and  $\alpha_8$  such that

$\alpha_5 + \alpha_6 = -6$  and  $\alpha_7 + \alpha_8 = -6$ , here the vertex sum is  $-6$ .

Fig 3

For case 2

Let  $k = 4$  and  $s = 1$

Fig 4

### 4.4 Corollary

$B_V(n_1, n_2, \dots, n_k)$  for  $k \geq 3$  is  $h$ -magic for  $h > k$  where  $k$  is the maximum of all edge labels.

### 4.5 Theorem

The chain of three cycles  $C(n_1, n_2, n_3)$  is group magic.

**Proof:**

Consider 3 cycles  $C_1, C_2$ , and  $C_3$ . Let  $u'$  be the vertex common to  $C_1$  and  $C_2$  and the vertex common to  $C_2$  and  $C_3$  be  $u''$ . Let the vertices adjacent to  $u'$  in  $C_1$  be  $u_1, v_1$ , those in  $C_2$  be  $u_2, v_2$  and the vertices adjacent to  $u''$  in  $C_2$  be  $u_2', v_2'$ , those in  $C_3$  be  $u_3, v_3$ .

We label the edges  $u'u_1, u'v_1, u'u_2$  and  $u'v_2$  as  $\alpha_1, \alpha_2, \alpha_3$ , and  $\alpha_4$  respectively. Choose  $\alpha$ 's from  $A^*$  such that the edge labels are nonzero.

To get the vertex sum as  $\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4$  at the vertices of  $C_1$  we label the other edges of  $C_1$  as  $\alpha_2 + \alpha_3 + \alpha_4$  and  $\alpha_1$  alternatively from the edge which is adjacent with  $u'u_1$ .

**Result:1**

If  $C_1$  is odd cycle the edge incident with  $v_1$  will receive the label as  $\alpha_2 + \alpha_3 + \alpha_4$ . To satisfy the magic condition at  $v_1$  we require

$$\alpha_2 + \alpha_3 + \alpha_4 + \alpha_2 = \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4.$$

Hence  $\alpha_2 = \alpha_1$ . Here the vertex sum is  $2\alpha_1 + \alpha_3 + \alpha_4$ .

**Result : 2**

If  $C_1$  is even, the edge incident with  $v_1$  will receive the label as  $\alpha_1$ .

The magic condition requires

$$\alpha_1 + \alpha_2 = \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4.$$

Hence  $\alpha_3 + \alpha_4 = 0$

This shows the edges  $u'u_2$  and  $u'v_2$  in  $C_2$  receives labels  $\alpha_3$  and  $-\alpha_3$ . Here the vertex sum is  $\alpha_1 + \alpha_2$ .

Fig 5

The above discussed results also hold for the cycle  $C_3$ . In  $C_2$  there are 2 paths joining  $u'$  and  $u''$ . Let them be  $P$  and  $Q$ . Now we see the labeling of  $G$  in the following cases.

**Case 1:**  $C_2$  even  $C_1$  and  $C_3$  are odd

By the result (1) the edges  $u''u_3$  and  $u''v_3$  in  $C_3$  receives the same label  $\alpha_1$ .

To get the vertex sum at the vertices of  $C_2$  as  $2\alpha_1 + \alpha_3 + \alpha_4$ , along  $P$  the edges of  $C_2$  can be labeled as  $2\alpha_1 + \alpha_4$  and  $\alpha_3$  alternatively from the edge which is incident with  $u_2$  and along  $Q$  the edges of  $C_2$  labeled as  $2\alpha_1 + \alpha_3$  and  $\alpha_4$  alternatively from the edge which is incident with  $v_2$ .

As  $C_2$  is even, both  $P$  and  $Q$  contain either odd or even number of edges. If both  $P$  and  $Q$  contain odd number of edges, along  $P, u_2'u''$  and along  $Q, v_2'u''$  gets the label as  $\alpha_3$  and  $\alpha_4$ . The remaining edges in  $C_3$  receive  $\alpha_1 + \alpha_3 + \alpha_4$  and  $\alpha_1$  alternatively. This labeling gives the vertex sum  $2\alpha_1 + \alpha_3 + \alpha_4$ .

As  $P$  and  $Q$  are the paths joining  $u'$  and  $u''$  and since  $G$  is a simple graph both  $P$  and  $Q$  cannot contain exactly one edge. So  $C_2$  must contain more than four edges. Refer figure 6.

If both  $P$  and  $Q$  contain even number of edges, along  $P, u_2'u''$  and along  $Q, v_2'u''$  gets the label as  $2\alpha_1 + \alpha_4$  and  $2\alpha_1 + \alpha_3$ .

To attain the magic condition at  $u''$ , the edges of  $C_3$  which are incident with  $u''$  must take the label as  $-\alpha_1$  and  $-\alpha_1$ . The remaining edges in  $C_3$  receive  $3\alpha_1 + \alpha_3 + \alpha_4$  and  $-\alpha_1$  alternatively.

In this case also the vertex sum is  $2\alpha_1 + \alpha_3 + \alpha_4$ . Refer figure 7.

**Case 2 :** All  $C_1, C_2$  and  $C_3$  are even.

From result (2)  $\alpha_4 = -\alpha_3$ . If both  $P$  and  $Q$  contain odd number of edges, along  $P, u_2'u''$  and along  $Q, v_2'u''$  gets the label as  $\alpha_3$  and  $-\alpha_3$ . Here  $\alpha_3$  should be chosen in such a way that  $\alpha_3 \neq$

$\alpha_1 + \alpha_2$ . The edges of  $C_1$  and  $C_3$  receive the labels  $\alpha_1$  and  $\alpha_2$  alternatively. Here the vertex sum is  $\alpha_1 + \alpha_2$ . Refer figure 8.

If both P and Q contain even number of edges, along P,  $u_2'u''$  and along Q,  $v_2'u''$  gets the label as  $\alpha_1 + \alpha_2 - \alpha_3$  and  $\alpha_1 + \alpha_2 + \alpha_3$ . Since  $C_3$  is even from result (2) we have  $\alpha_1 + \alpha_2 - \alpha_3 = -(\alpha_1 + \alpha_2 + \alpha_3)$ .

This shows  $\alpha_1 + \alpha_2 = 0$ . In this case the graph is zero sum magic.

**Case 3:  $C_2$  even and either  $C_1$  or  $C_3$  is odd.**

Suppose  $C_1$  is even from the result (2)  $\alpha_4 = -\alpha_3$ . If both P and Q contain odd number of edges, along P,  $u_2'u''$  and along Q,  $v_2'u''$  gets the label as  $\alpha_3$  and  $-\alpha_3$ . To attain the magic condition at  $u''$ , the edges of  $C_3$  which are incident with  $u''$  must take the label as  $\alpha_1$  and  $\alpha_2$ . Since  $C_3$  is odd by the result (1) we have  $\alpha_2 = \alpha_1$ . Hence the edges of  $C_2$  along P receive labels  $2\alpha_1 - \alpha_3$  and  $\alpha_3$  alternatively from the edge which is incident with  $u_2$  and those along Q receives  $2\alpha_1 + \alpha_3$  and  $-\alpha_3$  alternatively from the edge which is incident with  $v_2$ . Here  $\alpha_3$  should be chosen in such a way that  $\alpha_3 \neq 2\alpha_1$ . The remaining edges in  $C_3$  receive  $\alpha_1$ . This labeling gives the vertex sum  $2\alpha_1$ . Refer figure 9.

If both P and Q contain even number of edges, discussing as before in this case also the vertex sum is  $2\alpha_1$ . Refer figure 10.

**Case 4: All  $C_1, C_2$  and  $C_3$  are odd.**

By the result (1) the edges in  $C_1$  which are incident with  $u'$  receives the same label  $\alpha_1$ . Since  $C_2$  is odd either P or Q contains odd number of edges. Suppose P contain odd number of edges, the edge in P which is incident with  $u''$  receives  $\alpha_3$ . The edge in Q which is incident with  $u''$  receives  $2\alpha_1 + \alpha_3$ . The magic condition at  $u''$  requires the labels of edges of  $C_3$  incident with  $u''$  as  $\alpha_4$  and  $-\alpha_3$ . Since  $C_3$  is odd from result (1) we have  $\alpha_4 = -\alpha_3$ . In this case the vertex sum is  $2\alpha_1$  and  $\alpha_3$  should be chosen in such a way that  $\alpha_3 \neq 2\alpha_1$ . Suppose Q contain odd number of edges, same result derived from the similar argument. Refer figure 11.

**Case 5:  $C_2$  is odd and both  $C_1$  and  $C_3$  are even**

Since  $C_1$  is even, from the result (2)  $\alpha_4 = -\alpha_3$ . If P contains odd number of edges, the edge in P which is incident with  $u''$  receives  $\alpha_3$ . The edge in Q which is incident with  $u''$  receives  $\alpha_1 + \alpha_2 + \alpha_3$ . Since  $C_3$  is even from result (2) we have  $\alpha_1 + \alpha_2 + \alpha_3 = -\alpha_3$ .

Shows  $\alpha_3 = -(\alpha_1 + \alpha_2)/2$ .

Hence choosing  $\alpha_3$  as  $-(\alpha_1 + \alpha_2)/2$  the labeling is possible and it gives the vertex sum  $\alpha_1 + \alpha_2$ . Suppose Q contain odd number of edges, same result derived from the similar argument.

**Case 6:  $C_1, C_2$  are odd and  $C_3$  even**

By the result (1) the edges in  $C_1$  which are incident with  $u'$  receives the same label  $\alpha_1$ . If P contains odd number of edges, the edge in P which is incident with  $u''$  receives  $\alpha_3$ . The edge in Q which is incident with  $u''$  receives  $2\alpha_1 + \alpha_3$ . Since  $C_3$  is even from result (2) we have

$$2\alpha_1 + \alpha_3 = -\alpha_3.$$

And therefore  $\alpha_3 = -\alpha_1$ .

Hence choosing  $\alpha_3$  as  $-\alpha_1$  labeling is possible and it gives the vertex sum  $\alpha_1 + \alpha_4$ .  $\square$

### 4.7 Corollary

G is h - magic for  $h > k$  where k is the maximum of all edge labels.

### 4.8 Theorem

The chain of cycles  $C(n_1, n_2, \dots, n_k)$  is zero sum magic when k and all  $C_i$ 's are even.

**Proof:**

The case  $k = 2$  is in the case- 2 of theorem 4.1.

For  $i=1, 2, \dots, k-1$ , let  $u_i$  be the vertex common to  $C_i$  and  $C_{(i+1)}$  and let  $P_i$  and  $Q_i$  are the paths joining  $u_i$  and  $u_{(i+1)}$ .

Consider  $C(n_1, n_2, \dots, n_k)$  for  $k=4$ . The labeling of the graph is discussed as in theorem 4.5. From result (2) of theorem-4.5 the edges of  $C_1$  which are incident with  $u_1$  gets the labels  $\alpha_1$

and  $\alpha_2$  and the edges of  $P_1$  and  $Q_1$  which are incident with  $u_1$  gets labels  $\alpha_3$  and  $-\alpha_3$ . Since all cycles are even, for  $i=1,2$  and  $3$  both  $P_i$  and  $Q_i$  contains either even or odd number of edges.

Consider both  $P_i$  and  $Q_i$  contains even number of edges. In  $C_2$  if the edge of  $P_1$  and  $Q_1$  gets the label  $\alpha_3$  and  $-\alpha_3$  then the edge of  $P_1$  and  $Q_1$  which is incident with  $u_2$  gets the label  $\alpha_1+\alpha_2-\alpha_3$  and  $\alpha_1+\alpha_2+\alpha_3$ . To get the vertex sum at  $u_2$  as  $\alpha_1+\alpha_2$ , the edges of  $C_3$  incident with  $u_2$  gets  $-\alpha_1$  and  $-\alpha_2$ . The edges of  $C_3$  which are incident with  $u_3$  receive the label  $2\alpha_1+\alpha_2$  and  $\alpha_1+2\alpha_2$ . As  $C_4$  is even from result (2),  $2\alpha_1+\alpha_2+\alpha_1+2\alpha_2=0$ . This proves the vertex sum as zero.

Consider both  $P_i$  and  $Q_i$  contains odd number of edges. In  $C_2$  if the edge of  $P_1$  and  $Q_1$  gets the label  $\alpha_3$  and  $-\alpha_3$  then the edge of  $P_1$  and  $Q_1$  which is incident with  $u_2$  also gets the label  $\alpha_3$  and  $-\alpha_3$  respectively. To get the vertex sum at  $u_2$  as  $\alpha_1+\alpha_2$ , the edges of  $C_3$  incident with  $u_2$  gets  $\alpha_1$  and  $\alpha_2$ . The edges of  $C_3$  which are incident with  $u_3$  receive the label  $\alpha_1$  and  $\alpha_2$ . As  $C_4$  is even from result (2),  $\alpha_1+\alpha_2=0$ . This proves the vertex sum as zero.

Suppose both  $P_1$  and  $Q_1$  contains even number of edges and both  $P_2$  and  $Q_2$  contains odd number of edges. Discussing the edge labels as above the edge of  $P_1$  and  $Q_1$  which is incident with  $u_2$  gets the label  $\alpha_1+\alpha_2-\alpha_3$  and  $\alpha_1+\alpha_2+\alpha_3$ . To get the vertex sum at  $u_2$  as  $\alpha_1+\alpha_2$ , the edges of  $C_3$  incident with  $u_2$  gets  $-\alpha_1$  and  $-\alpha_2$ . The edges of  $C_3$  which are incident with  $u_3$  receive the label  $-\alpha_1$  and  $-\alpha_2$ .

Similarly we can prove for any even number  $k$ , the labeling of the graph  $C(n_1, n_2, \dots, n_k)$  as discussed in the above two cases will give the vertex sum as zero.  $\square$

#### 4.9 Theorem

Let  $C(n_1, n_2, \dots, n_k)$  be a chain of  $k$  cycles  $C_j$  with  $k$  is odd and all  $C_j$ 's are even. For  $i = 1, 2, \dots, k-2$ , let  $P_i$ 's and  $Q_i$ 's are the paths in the cycle  $C_{(i+1)}$  connecting the vertices  $u_i$  and  $u_{(i+1)}$  where the vertex  $u_i$  is common to  $C_i$  and  $C_{(i+1)}$  and the vertex  $u_{(i+1)}$  is common to  $C_{(i+1)}$  and  $C_{(i+2)}$ . If  $P$ 's and  $Q$ 's contains odd number of edges then  $C(n_1, n_2, \dots, n_k)$  is group magic and if  $P$ 's and  $Q$ 's contains even number of edges then  $C(n_1, n_2, \dots, n_k)$  is zero sum magic.

**Proof:**

As the end cycle  $C_1$  is even by result (1) of theorem 4.5 the edges of  $C_1$  which are incident with  $u_1$  gets the labels  $\alpha_1$  and  $\alpha_2$  and the edges of  $P_1$  and  $Q_1$  which are incident with  $u_1$  gets labels  $\alpha_3$  and  $-\alpha_3$ . Since all cycles are even, for  $i=1, 2, \dots, k-2$ , both  $P_i$  and  $Q_i$  contains either even or odd number of edges.

Consider all  $P_i$ 's and  $Q_i$ 's contains odd number of edges. The edges of  $P_1$  and  $Q_1$  incident with  $u_2$  get the labels  $\alpha_3$  and  $-\alpha_3$  and the edges of  $P_2$  and  $Q_2$  incident with  $u_2$  gets the labels  $\alpha_1$  and  $\alpha_2$ . Since  $P_2$  and  $Q_2$  contains odd number of edges, the edges of  $P_2$  and  $Q_2$  incident with  $u_3$  get the labels  $\alpha_1$  and  $\alpha_2$  and the edges of  $P_3$  and  $Q_3$  incident with  $u_3$  gets the labels  $\alpha_3$  and  $-\alpha_3$ . Continuing in the same way it can be observed that the edges of  $P_{k-1}$  and  $Q_{k-1}$  incident with  $u_{k-1}$  gets the labels  $\alpha_3$  and  $-\alpha_3$  and the edges of  $C_k$  incident with  $u_{(k-1)}$  gets the labels  $\alpha_1$  and  $\alpha_2$  since  $k$  is odd. Thus at all vertices the vertex sum is  $\alpha_1+\alpha_2$ .

Consider all  $P_i$ 's and  $Q_i$ 's contains even number of edges. The edges of  $P_1$  and  $Q_1$  incident with  $u_2$  get the labels  $\alpha_1+\alpha_2-\alpha_3$  and  $\alpha_1+\alpha_2+\alpha_3$  and the edges of  $P_2$  and  $Q_2$  incident with  $u_2$  gets the labels  $-\alpha_1$  and  $-\alpha_2$ . Since  $P_2$  and  $Q_2$  contains even number of edges, the edges of  $P_2$  and  $Q_2$  incident with  $u_3$  get the labels  $2\alpha_1+\alpha_2$  and  $\alpha_1+2\alpha_2$  and the edges of  $P_3$  and  $Q_3$  incident with  $u_3$  gets the labels  $-2\alpha_1$  and  $-2\alpha_2$ . Continuing in the same way it

can be observed that the edges of  $P_{k-1}$  and  $Q_{k-1}$  incident with  $u_{k-1}$  gets the labels  $(k-2)\alpha_1+\alpha_2$  and  $\alpha_1+(k-2)\alpha_2$  since  $k$  is odd. Since  $C_k$  is even from result (2) of theorem 4.5, we have  $(k-2)\alpha_1+\alpha_2+\alpha_1+(k-2)\alpha_2=0$ .

This shows the vertex sum  $\alpha_1+\alpha_2$  is zero.  $\square$

## 5. CONCLUSION AND FUTURE WORK

In theorems 4.1 and 4.2 it was derived that in group magic labeling of  $B_V(n_1, n_2, \dots, n_k)$  the vertex sum contains as many distinct labels as many odd cycles. The vertex sum is zero when all cycles are even. The chain of cycles  $C(n_1, n_2, \dots, n_k)$  is group magic when there are odd number of cycles in  $C(n_1, n_2, \dots, n_k)$  also the path connecting the common vertices have odd number of edges. The chain of cycles  $C(n_1, n_2, \dots, n_k)$  is zero sum magic when there are even number of even cycles in  $C(n_1, n_2, \dots, n_k)$  and also in the case that there are odd number of cycles in  $C(n_1, n_2, \dots, n_k)$  and the path connecting the common vertices have even number of edges. We further work to derive the group magic labeling to the chain of cycles  $C(n_1, n_2, \dots, n_k)$  in the remaining cases.
