ABSTRACT

Interval graphs have drawn the attention of many researchers for over 30 years. They are extensively been studied and revealed their practical relevance for modeling problems arising in the real world. The theory of domination in graphs is an enriching area of research at present. In this paper we discuss matching domination number of interval graphs and propose an algorithm for finding matching dominating sets in interval graphs.

Keywords

Interval graph, dominating set, matching dominating set and neighbourhood set

Subject Classification: 68R10

1. INTRODUCTION

The theory of domination in graphs was introduced by Ore [1] and Berge [2] and it has become an emerging area of research in graph theory today. A survey on results and applications of dominating sets was presented by E.J.Cockayne and S.T.Hedetmiemi [3].

Let $G(V, E)$ be a graph. A subset D of V is said to be a dominating set of G if every vertex in $V \setminus D$ is adjacent to a vertex in D . The domination number $\gamma(G)$ of G is the minimum cardinality of a dominating set. A matching in a graph G is a subset M of edges of E such that no two edges in M are adjacent. A matching M in G is called a perfect matching if every vertex of G is incident to some edge in M .

A dominating set D of G is said to be a matching dominating set if the induced subgraph $\langle D \rangle$ admits a perfect matching. The cardinality of the smallest matching dominating set is called matching domination number and is denoted by γ_m .

2. INTERVAL GRAPH

Let $I = \{1, 2, \dots, n\}$ be an interval family where each i in I is an interval on the real line and $i = [a_i, b_i]$ for $i = 1, 2, \dots, n$. Here a_i is called the left endpoint and b_i is called the right endpoint of i . Without loss of generality, we assume that all endpoints of the intervals in I are distinct numbers between 1 and $2n$. The intervals are labeled in increasing order of their right endpoints. Two intervals i and j are said to intersect each other if they have non-empty intersection.

Let $G(V, E)$ be a graph. G is called an interval graph if there is a one-to-one correspondence between V and I such that two vertices of G are joined by an edge in E if and only if their corresponding intervals in I intersect.

Let G be the interval graph corresponding to the interval family I . Let $nbnd[i]$ be defined as the set of vertices adjacent to i including i . Let $min(i)$ denote the smallest interval in

$nbnd[i]$ and $max(i)$ denote the largest interval in $nbnd[i]$. Define $Next(i) = j$ if and only if $b_i < a_j$ and there does not exist an interval k such that $b_i < a_k < a_j$. If there is no such j , we define $next(i) = null$.

We proceed in the following manner to find a minimum matching dominating set of an interval graph.

Define $u(i) = max(Next(i))$ and $mate(i) = max(nbd(i))$. If $Next(i) = null$, then $u(i) = null$. Let LI denote the largest interval in S . Then the following Algorithm finds a minimum matching dominating set of an interval graph.

3. ALGORITHM : MMDS – IG

Input : Interval family $I = \{1, 2, \dots, \dots, n\}$.

Output : Minimum Matching dominating set of the interval graph G .

Step 1 : Let $S = \{max(1), mate(max(1))\}$.

Step 2 : $LI =$ The largest interval in S .

Step 3 : Compute $u(LI)$.

Step 4 : If $u(LI) = null$ then go to step 5

else

$S = S \cup \{u(LI), mate(u(LI))\}$

go to step 2.

Step 5 : End

4. MAIN RESULTS

Lemma 1: If i and k are any two intervals which are intersecting and j is any interval such that $i < j < k$ then j intersects k .

Proof : Since the intervals are labeled in increasing order of their right end points, it is easy to see that when $i < j < k$ then $b_i < b_j < b_k$. Now i intersects k implies that $a_k < b_i$. Therefore $a_k < b_i < b_j < b_k$ which implies that j also intersects k .

Lemma 2: If i is any interval and j such that

$i < j < mate(i)$, then j intersects $mate(i)$.

Proof : By the definition of $mate(i)$, it is the largest interval in $nbnd(i)$ and it intersects i . Therefore it follows by

Lemma 1 that, if j is any interval such that $i < j < \text{mate}(i)$ then j intersects $\text{mate}(i)$.

Lemma 3 : The intervals between i and $\text{mate}(i)$ are dominated by $\text{mate}(i)$.

Proof : Follows by Lemma 2.

Lemma 4 : If i is any interval and $j = u(i) = \max(\text{Next}(i))$ then the intervals between i and j are dominated by either i or j .

Proof : Let k be an interval between i and j .

Case 1 : Suppose i does not intersect k . Then $b_i < a_k$.

Let $\text{Next}(i) = h$. Then two possibilities arise.

Either $b_k > b_h$ or $b_k < b_h$.

Subcase 1 : Suppose $b_k < b_h$

Then $\text{Next}(i) = k$, so that $h = k$.

Since $j = u(i) = \max(\text{Next}(i)) = \max(k)$,

it follows that k intersects j .

Subcase 2 : Suppose $b_k > b_h$

Since $j = \max(\text{Next}(i)) = \max(h)$, h intersects j and $h < j$.

Now $b_k > b_h$ implies $h < k$. Therefore h intersects j and

$h < k < j$ implies by Lemma 1 that k intersects j .

Thus in either case k is dominated by j .

Case 2: Suppose k does not intersect j .

Subcase 1 : Suppose j intersects i . Then $a_j < b_i$. Since k does not intersect j we have $b_k < a_j$ so $b_k < a_j < b_i$.

By hypothesis $i < k < j$, so $a_i < a_k$.

Therefore $a_i < a_k < b_k < b_i$ and hence k intersects i .

Subcase 2 : Suppose j does not intersect i . Then k must intersect i , otherwise k becomes the first non-intersecting interval i.e., $\text{Next}(i) = k$. Since $j = u(i) = \max(\text{Next}(i)) = \max(k)$, it follows that k intersects j , a contradiction to our assumption. Therefore k must intersect i . Thus in either case k is dominated by i .

Therefore if k is any interval between i and j where

$j = u(i) = \max(\text{Next}(i))$ then k is dominated by either i or j .

Theorem 1 : The set S produced by the Algorithm is a matching dominating set of the given interval family.

Proof : Let I be the given interval family and G its corresponding interval graph. Let S be the set constructed by the Algorithm.

Suppose $S = \{i_1, i_2, \dots, i_k\}$.

Here $i_1 = \max(I)$ and $i_2 = \text{mate}(i_1)$. So there is an edge between i_1 and i_2 . Now $i_3 = u(i_2)$ and $i_4 = \text{mate}(i_3)$.

Hence there is an edge between i_3 and i_4 .

Likewise $i_k = \text{mate}(i_{k-1})$ and so there is an edge between i_k and i_{k-1} . Now $i_3 = u(i_2)$. So there is no edge between i_2 and i_3 . Hence there are no edges between i_2 and i_3 , i_4 and i_5, \dots, i_{k-2} and i_{k-1} . By the construction of S , it is clear

that there are an even number of edges in the induced sub graph $\langle S \rangle$. Therefore $\langle S \rangle$ has a perfect matching.

Hence S is a matching dominating set of given interval graph.

Theorem 2 : The matching dominating set constructed by the Algorithm is minimum.

Proof : Let $S = \{i_1, i_2, \dots, i_k\}$ be the matching dominating set constructed by the algorithm.

Let $S_1 = \{j_1, \dots, j_m\}$ be a minimum matching dominating set of G . We show that $|S_1| = |S_2|$.

Without loss of generality assume that $j_1 < j_2 < \dots < j_m$.

Since the vertices in S_1 dominate the vertices in G and S_1 is also minimum, it follows from $i_1 = \max(I)$ and $i_2 = \text{mate}(i_1)$ that $j_1 \leq i_1, j_2 \leq i_2$. Since $i_3 = u(i_2)$, by a similar argument it follows that $j_3 \leq i_3$ or

$i_3 \leq j_3$. But $j_4 \leq i_4$ and the argument continues like this. That is between every pair of vertices (i_{2r-1}, i_{2r}) of S , there is a vertex j_{2r} from S_1 such that $j_{2r} \leq i_{2r}$. Since the number of vertices in S_1 is even, we take $m = 2l$ for some $l > 0$. If $m < k$, then the vertices after i_{2l} (here $j_m = j_{2l} \leq i_{2l}$) will not be dominated by any vertex in S_1 . Therefore we must have $m = k$. Hence the matching dominating set constructed by the algorithm is minimum.

5. CONCLUSION

It is interesting to find various graph theoretic concepts of Interval graphs. The authors have studied inverse dominating sets [4], global neighbourhood sets [5], accurate and total accurate dominating sets and bondage numbers of these graphs. Finding matching dominating sets of Interval graphs will enrich the study this concept in Circular-arc graphs and Overlap graphs. An algorithmic approach gives scope and makes easier to characterize these graphs.

6. ILLUSTRATION

Fig.1

Interval Family I

Fig.2

Interval Graph G

$$\text{nbd}(1) = \{2,3\}$$

$$\text{max}(1) = 3 \quad \text{Next}(1) = 4 \quad u(1) = 6$$

nbd(2)	=	{1,3,4}	max (2) = 4	Next(2) = 5	u(2) = 6
nbd(3)	=	{1,2,4}	max (3) = 4	Next(3) = 5	u(3) = 6
nbd(4)	=	{2,3,5,6}	max (4) = 6	Next(4) = 7	u(4) = 9
nbd(5)	=	{4,6}	max (5) = 6	Next(5) = 7	u(5) = 9
nbd(6)	=	{4,5,7}	max (6) = 7	Next(6) = 8	u(6) = 10
nbd(7)	=	{6,8,9}	max (7) = 9	Next(7) = 10	u(7) = 12
nbd(8)	=	{7,9,10}	max (8) = 10	Next(8) = 11	u(8) = 12
nbd(9)	=	{7,8,10,11,12}	max (9) = 12	Next(9) = null	u(9) = null
nbd(10)	=	{8,9,11,12}	max (10) = 12	Next(10) = null	u(10) = null
nbd(11)	=	{9,10,12}	max (11) = 12	Next(11) = null	u(11) = null
nbd(12)	=	{9,10,11}	max (12) = 11	Next(12) = null	u(12) = null

Input : Interval family given in Fig.1.

Step 1 : $S = \{\max(1), \text{mate}(\max(1))\}$
 $= \{3, \max(\text{nbd}(3))\}$
 $= \{3, 4\}$

Step 2 : LI = Largest interval in $S = 4$

Step 3 : $u(\text{LI}) = \max(\text{Next}(4))$
 $= \max(7)$
 $= 9$

Step 4 : $u(\text{LI}) \neq \text{null}$. So
 $S = S \cup \{u(\text{LI}), \text{mate}(u(\text{LI}))\}$
 $= \{3,4\} \cup \{9, \max(\text{nbd}(9))\}$
 $= \{3,4\} \cup \{9,12\} = \{3,4,9,12\}$
 go to Step 2

Step 2 : LI = 12

Step 3 : $u(\text{LI}) = \max(\text{Next}(12)) = \text{null}$
 go to Step 5

Step 5 : End.

Output : $S = \{3, 4, 9, 12\}$ is the minimum matching dominating set of the interval graph given in Fig. 2.
